Does cyclic GMP mediate the slow excitatory synaptic potential in sympathetic ganglia?

THE slow excitatory postsynaptic potential (slow EPSP) of vertebrate sympathetic ganglia is elicited by the muscarinic action of acetylcholine^{1,2}. Its electrogenic mechanism appears strikingly different from that of the well-known (fast) EPSP in many respects—most notably that it is generated with no detectable increase in membrane conductance³. As this type of transmitter action is probably related to cholinergic processes in the brain^{4,5} and possibly in the spinal cord⁶, further study of the slow EPSP in the ganglia as a simpler model of the central cholinergic pathways is of great significance.

It has been proposed that cyclic guanosine monophosphate (cyclic GMP) mediates muscarinic acetylcholine action in various tissues⁷. However, to establish this hypothesis more adequately in sympathetic ganglion cells, it is crucial that the observed postsynaptic depolarisation induced by cyclic GMP⁸ be developed with membrane changes which are identical to those accompanying the slow EPSP itself. We have now used intracellular tests to show that cyclic GMP can elicit two kinds of depolarising response, one of which shows at least some similarity to the slow EPSP.

Intracellular recordings were made in the rabbit superior cervical ganglion at 34 °C, with microelectrodes filled with 1M-KCl, by methods generally the same as those already described⁹.

Extracellular application of cyclic GMP produced a steady depolarisation, but the accompanying changes in membrane resistance (r_m) were different for different ranges of concentration. (Data are all with dibutyl ester; non-butyryl cyclic GMP behaved similarly but required higher concentrations.) With lower concentrations (25 to 100 μ M) of cyclic GMP, r_m seemed somewhat decreased, with initial phase of depolarisation that reached a maximum to about 7 mV (Fig. 1, A-a). But this decrease in r_m tended to subside thereafter, whereas the depolarisation was sustained. On the other hand, when the membrane potential was clamped to the original resting level (Fig. 1, B-a) by applying steady polarising current, no decrease in r_m was observed during the action of cyclic GMP. This suggests that cyclic

GMP action itself produced essentially no decrease in r_m , and that the small decrease in r_m during the initial depolarisation of non-polarised cell might be due to a delayed rectification effect (increase in K permeability) produced by the slow depolarisation *per se*. This supposition is better tested by measuring the current-voltage relationship (I-V curve) and comparing the slope of the curves before and during cyclic GMP depolarising action (Fig. 1C). The slope of the I-V curve was found not reduced by cyclic GMP, indicating there was no decrease in r_m . When some flattening of the I-V curves were recorded in the depolarised range, there was rather slight increase in the slope with cyclic GMP. This apparent reduction of the delayed rectification seems to become more marked at 5-10 min after the onset of exposure of the ganglion to cyclic GMP. A similar increase in r_m was reported to occur in single cortical cells of the cat after the intracellular injection of cyclic GMP^{10,11}.

With approximately 10-fold higher concentrations of cyclic GMP, 500-1,000 μ M, the depolarisation was not only distinctly greater (about twofold or more), but it was now accompanied by a substantial decrease in r_m (Fig. 2A) which could not be abolished by repolarising the membrane to the

Fig. 1 Changes in membrane potential and resistance in response to lower concentrations of cyclic GMP, or to orthodromic nerve stimulation. Resting potential was -51 mV. A-a, response to stimulation at 100 μ M (horizontal bar); B-a, slow dibutyl-cyclic GMP maximal preganglionic nerve stimuli at EPSP elicited by curarine, 20 μ g ml⁻¹, was present to block 20/s (bar). (b). Membrane resistance was monitored by the fast EPSP voltage pulses resulting from the passage across size of range of constant current pulses (1 s) at a frequency of 0.5 s⁻¹ during the course of each depolarisation as seen in resting B-b; this was done by passing a steady hyperpolarising current with manual controls. Calibration: 10 mV and 10 s. C, Current-voltage (I-V) relationship obtained from the same cell in A and B, before (open circles) and 10 min after (filled circles) the application of cyclic GMP (100 μ M). A zero level of the ordinate indicates the resting potential without cyclic GMP. D, Electrotonic potentials (lower records of each pair) induced by the current pulses (upper records) of different strengths and polarity. Data correspond to the I-V curves shown in C. Pulses were passed across the membrane at the resting potential level (column a) and at the top of steady depolarisation by 100 μ M cyclic GMP (column b). Most of the cells gave 'humped' tonic responses to the passage of weak polarising currents, as seen by Blackman *et al.*¹⁸, so that the potential heights were measured at the steady plateau level when plotted in the graph in C. Calibration: 0.25 nA (hyperpolarising direction upwards) for currents and 25 mV (hyperpolarisation down) for potentials; 0.5 s time-base.

Fig. 2 Changes in membrane potential and resistance in response to higher concentration of cyclic GMP. Resting potential was -53 mV. Frequency of current pulses (200 ms duration in this case) to monitor the membrane resistance was 0.2/s. Calibration: 20 mV and 5 s. *A*, Depolarisation induced by cyclic GMP at $1,000 \mu\text{M}$; *B*, I-V relationships obtained from the same cell, with cyclic GMP (filled circles) and without (open circles).

resting potential level. Further evidence that this marked decrease in r_m is due to the action of cyclic GMP itself is seen in the altered slope of the I-V curve (Fig. 2*B*). The roughly linear portions of the I-V curves near the resting potential indicate a drop in r_m of more than 50% during cyclic GMP action. This second type of depolarising action by stronger cyclic GMP may be a more nonspecific one; it may be related to the responses with increased conductance which can be elicited by either cyclic GMP or cyclic AMP^{11,12}, and to the depolarisation of peripheral nerve by higher concentrations of cyclic GMP⁸.

The difference in r_m effects for low against high cyclic GMP is not simply a quantitatively graded one, related to the magnitude of depolarising action; although the minimum concentration to produce a detectable reduction in r_m appears somewhat variable from cell to cell with the range between 100 – $500 \mu\text{M}$, in a given cell there was always a distinct range of low concentration in which no detectable change in r_m accompanied a definite depolarisation by cyclic GMP.

During the slow EPSP depolarisation there was little or no change in r_m as reported previously³ (Fig. 1*B*). However, when the membrane potential during the slow EPSP response was temporarily repolarised to the resting level, a definite but small increase in r_m (about 20%) above resting level was usually visible (Fig. 1, *B*, but 20%) above resting level). Actually, determination of full (see also refs 3, 5, 6, 13). cell during muscarinic transmitter action reveals that (1) resistance (slope) is essentially unchanged from that seen for the control I-V curve with no muscarinic action and (2) in the depolarised range there is a substantial increase in r_m , but it only brings the slope back towards though no slope, that in the hyperpolarised range of control curve. This relationship to r_m is similar to that described for the hyperpolarised range of control curve. Thus the increase in r_m produced by muscarinic action in the depolarised range is best explained as an action antagonistic to the delayed rectification effect of depolarisation. This may be due to an action resembling the tetraethylammonium antagonism of delayed rectification¹⁵.

The postsynaptic depolarising action of a low concentration of cyclic GMP was thus found to resemble in its electrogenic nature the slow EPSP in one respect: both show no increase in membrane conductance. Indeed, if elicited in a somewhat hyperpolarised range of membrane potential

levels of -60 to -70 mV, which are probably normal ranges of resting potential of unimpaled cells, the depolarising responses to both muscarinic acetylcholine and the low concentration of cyclic GMP develop with neither increase nor decrease in membrane conductance. On this basis, there is at least some support for the hypothesis^{7,8} that the specific postsynaptic receptor for the slow EPSP response to acetylcholine operates by activating guanylate cyclase, leading to an increase in cellular cyclic GMP, (refs 16, 17, H.K. and N.S.U., unpublished) which in turn induces the subsequent depolarising response. Furthermore, this possibility of the involvement of intracellular cyclic GMP synthesis in the generation of the slow EPSP is in general agreement with our previous observation that the slow EPSP is quite selectively sensitive to the depression of oxidative metabolism^{1,3}.

Postsynaptic modulation of excitatory process in sympathetic ganglia by cyclic AMP

THE principal neurones of the vertebrate sympathetic ganglia usually respond to suitable preganglionic stimuli with three types of temporally distinguishable postsynaptic potential (PSPs) in the following sequence: an initial excitatory one (fast EPSP), a slow inhibitory one (slow IPSP) and a slow excitatory one (slow EPSP)^{1,2}. These three responses can also be distinguished pharmacologically: the fast EPSP is mediated by a nicotinic acetylcholine receptor, and the slow EPSP by a muscarinic acetylcholine receptor. The synaptic pathway of the slow IPSP includes intervening adrenergic cells (called “SIF” cells³) which release a catecholamine transmitter (identified as dopamine in the case of rabbit^{4,5}), in response to the muscarinic action of acetylcholine, and in turn depolarise the ganglion cells.

It has been found that the brief application of dopamine to exhibit superior cervical ganglion produces prolonged agonism of the depolarisation induced by a muscarinic monophase can be mimicked by exogenous cyclic adenosine iontophoretically (cyclic AMP)⁷. We have now found that injected cyclic AMP into the single ganglion

cell can induce a long-lasting enhancement of the physiologically-elicited slow EPSP. Repetitive stimulation of the preganglionic nerve, in a manner shown to release dopamine from the SIF cells intraganglionically⁴ and to raise ganglionic cyclic AMP^{8,9}, was also found capable of inducing the similar change in the slow EPSP.

Isolated superior cervical ganglia of rabbit were studied at 34 °C, utilising conventional microelectrophysiological techniques¹⁰. For iontophoretic injections, the microelectrode was filled with 0.9M KCl plus 0.1M cyclic AMP (K-salt) and had tip resistance of 40 to 60M Ω . To inject cyclic AMP, 0.5nA was passed for 3 to 10 min.

Following intracellular injection of cyclic AMP, re-tests of the slow EPSP showed enhancement in 4 out of 9 cells tested. A typical example of such an effect is seen in Fig. 1. Amplitudes increased to a maximum after about 15–20 min and then decayed gradually, returning to control levels almost 2 h later. During the enhanced slow EPSPs, there were no appreciable or consistent changes in the partially curarised fast EPSPs responding to the orthodromic volleys; nor were there any significant changes in resting membrane potential or resistance. A second injection of cyclic AMP could renew the enhancement of the slow EPSP (Fig. 1). The absence of effects in some of the nine cells tested could be due partly to the marginally small amounts of cyclic AMP injected in the present method.

Control injections of current alone with a KCl-only micro-electrode in 10 other cells or more produced no such changes in the slow EPSP in the ensuing 2 h. Similarly, with electrodes containing adenosine (non-cyclic) 5'-monophosphate or adenosine triphosphate (ATP) no slow EPSP changes were observed.

A similar change in the slow EPSP could also be induced by the extracellular application of dibutyryl cyclic AMP (1 to 2.5mM added to the chamber bath for 4–8 min) in most of the ganglion cells tested. The absence of any direct hyperpolarising response to dibutyryl cyclic AMP itself, at a concentration which did produce a long-lasting enhancement of the slow

Fig. 1 Slow EPSP amplitude (filled circles) and membrane resistance (open circles) after intracellular injection of cyclic AMP. Current of 0.5nA to inject cyclic AMP iontophoretically was passed between the arrows. Each slow EPSP was evoked at 3- to 10-min intervals by a train of supramaximal preganglionic nerve stimuli (20/s for 1 s), in the presence of d-tubocurarine (20 μ g ml⁻¹) to depress the fast EPSPs. Resting membrane potential of this cell was -50mV. The cell recorded stably for more than 4 h. Inset on the right shows actual oscillograms of the slow EPSPs that correspond to the lettered points on the graph. Stimulation was given at the arrow. Calibration: 5mV and 5 s.

Membrane resistance (ordinate on right side) was measured from the plateau amplitude of the change in membrane potential produced by a constant current hyperpolarising pulse (1 s duration). All exogenous currents were passed through the recording electrode by means of a Wheatstone bridge arrangement. In this and most other experiments with cyclic AMP, the intraganglionically releasable dopamine in the whole ganglion was depleted by a pretreatment with bethanechol⁷, and therefore the slow IPSP were not seen in the oscillograms. This minimises possible effects of dopamine that could be synaptically released during the experimental period, and simplifies the interpretation of changes in the slow EPSPs.

Fig. 2 Slow EPSP and membrane resistance after conditioning stimulation of preganglionic nerve (20/s supramaximal for 1 min, at the arrow) and after a later intracellular injection of cyclic AMP (between arrows). Resting membrane potential was -52mV. Otherwise as in Fig. 1, except that this ganglion was not pretreated with bethanechol, in order that synaptically releasable dopamine remains available. The latter accounts for the normally appearing slow IPSP component before the main slow EPSP in the responses shown by the oscillogram records.

EPSP, is in agreement with other studies using intracellular recordings^{11,12,19}; apparent hyperpolarising responses have been reported with the sucrose-gap technique by some¹³, but not others¹⁴.

Conditioning stimulation with repetitive preganglionic volleys (20/s for 1 min) could also be followed by a period of enhanced slow EPSPs as shown in Fig. 2. The slow EPSPs rose to more than 200% of control value at about 25 min after the conditioning, returning slowly to the original level after about 90 min. The postconditioning modulatory change also occurred without significant changes in resting membrane potential or resistance of the ganglion cell (Fig. 2). In these experiments, post-tetanic potentiation of presynaptic function could contribute to the changes, but this factor was apparently significant only during the initial 10–15 min after conditioning; this could be judged primarily from changes in the fast EPSPs, since presynaptic PTP should presumably affect both the fast and slow EPSPs similarly¹⁵. Furthermore, in some cells there happened to be no detectable slow IPSP, indicating that orthodromic volleys were ineffective in delivering functionally sufficient dopamine by release from the SIF cells⁴; in these cells the conditioning stimulation produced an increase lasting only about 15–20 min in all of the postsynaptic responses, without any longer lasting enhancement in the slow EPSP.

With surface recordings from the whole ganglion similar long-lasting modulatory effects of preganglionic conditioning were observed; in the five ganglia tested, the population slow EPSP response showed enhancement for periods of almost 3 h, with maximal increases of an average of $+60\% \pm 10.2\%$ (range $+39\% - +95\%$). Related long-lasting enhancements of muscarinically-induced postganglionic firing have also been reported to follow a conditioning train of preganglionic volleys, in superior cervical ganglia of the cat *in vivo*¹⁶, and of the rat *in vitro*¹⁷.

Our results provide further support for the proposal of Libet *et al.*⁷ that at least one of the two postsynaptic actions of dopamine, the long-lasting enhancement of the muscarinic depolarising response, may be mediated intracellularly by cyclic AMP. This effect is now demonstrable with slow EPSP responses of the single ganglion cell; it can be produced by intracellularly injected cyclic AMP, eliminating any question of an indirect action of cyclic AMP through a presynaptic release of the other transmitter(s); it is producible through the more physiological route of orthodromic nerve impulses as well as by applied dopamine or cyclic AMP. The absence of significant changes in resting membrane potential or resistance, during enhanced slow EPSP, helps to establish further the effect as an actual modulatory change in the intraneuronal mechanisms

that generate the slow EPSP response to acetylcholine. On the other hand, the absence of a direct hyperpolarising response of the single cell to extracellularly applied dibutyryl cyclic AMP, even at 2.5 mM or more (see also^{11,13}), raises a serious question about the proposed role for cyclic AMP^{13,18} as the mediator of the slow IPSP.

Ecto-ATPase deficiency in glia of seizure-prone mice

A DEFICIENCY of calcium-stimulated adenosine triphosphatase (Ca^{2+} -ATPase) is seen in brains of mice which are susceptible to audiogenic seizures¹. After studying five other animal models of idiopathic epilepsy we concluded that brain nucleotide metabolism is altered in the epileptic animals and that the lesion might not be confined to Ca^{2+} -ATPase². We speculated that the deficiency of Ca^{2+} -ATPase, which we observed in membrane-enriched brain homogenates, was the expression of incompetent brain cell ecto-ATPases. We have suggested that the genesis of seizures was related to a protracted action of translocated cytoplasmic ATP on cell membranes³ when the latter were deficient in this enzyme. We report here a significant deletion of ecto-ATPase in cultured glia cells raised from neonatal, seizure-prone mice. Between the ages of 20 to 35 d, mice of the DBA/2N strain convulse after repeated exposure to loud noise. Before and after this period, susceptibility to induced convulsions is minimal or absent. Mice of the C57 B1/6N strain are not afflicted in this manner.

Fig. 1 Ecto-ATPase activity of normal and seizure-prone mouse glia cells. Cells of passage 4 from C57 mouse brains (solid symbols) and from DBA mouse brains (open symbols) were plated out at equal density in 9.6-cm² multi-dish tissue culture trays (Linbro). The cell monolayers were rinsed with 2 ml of modified Dulbecco's medium (mDMEM) and then incubated for 15 min with 2 mM ATP- γ -³²P in mDMEM (see Table 1). Medium was removed after incubation and the cells digested for 24 hours with 1 N NaOH. Protein in the digest was determined according to Lowry *et al.*¹⁰. Each point shown is the average of three determinations. Cultures were assayed at day 7 (●, ○), 11 (■, □) and 18 (▲, △). Curve fitting was by least squares, quadratic polynomials.

Ten separate glia cell cultures (largely of astroblast origin) were obtained from explants of newborn mouse brains according to the procedure of Shein *et al.*⁴. The cultures obtained from neonatal DBA mice (epileptic) are designated D lines and those from the C57 mice (controls), C lines. Experiments were performed on cell cultures of five different D clones and five different C clones after the lines had been propagated through three passages.

Ecto-ATPase assays were performed on intact monolayer cultures which were superfused with substrate in an iso-osmotic medium the composition of which closely resembled the culture medium. The assay of ectoenzyme activity required appropriate conditions and controls (see refs 5, 6). We also determined the activities of ecto-5'-nucleotidase, ecto-ADPase and *p*-nitrophenyl phosphatase (though it is not certain that the latter indeed is an ectoenzyme). Here, as in our earlier experiments with membrane-enriched brain fractions from DBA, C57 and C3H mice¹ these enzymes served as controls and attested to membrane integrity. The specific activity of some ectoenzymes (mol of substrate metabolised per unit time per mg of protein) can vary greatly with the cell density of cultures or with their proliferative rate⁹. Some of the enzyme assays, therefore, were

Table 1 Conditions for assay of ecto-enzymes

Enzyme	Assay medium	Substrate	Product analysed	Refs
Adenosine-triphosphatase (EC 3.6.1.3)	0.5 ml mDMEM* pH 7.4	2 mM ATP- γ - ³² P	liberated ³² PO ₄	7
Adenosine-diphosphatase (EC 3.1.3.5)	0.5 ml phosphate-free buffer, pH 7.4	1 mM ADP	PO ₄ (colorimetric)	8
5'-Nucleotidase (EC 3.1.3.5)	0.5 ml mDMEM pH 7.4	1 mM AM ³² P	liberated ³² PO ₄	7
<i>p</i> -Nitrophenyl-phosphatase (EC 3.1.3.1)	1.0 ml phosphate-free buffer pH 7.4	1 mM Tris- <i>p</i> -nitrophenylphosphate	<i>p</i> -nitrophenol (colorimetric)	5

Cells grown to confluency in 9.6-cm² multi-dish trays were rinsed with mDMEM or phosphate-free buffer⁵ before incubation. Monolayers were then incubated for 15–60 min at 37 °C and rotated horizontally at 50 r.p.m. every 90 or 180 s for 6 s.

*Modified Dulbecco's minimum essential medium; it contained neither foetal calf serum nor indicator dyes; Ca^{2+} was 0.5 mM and Mg^{2+} was 5 mM.

Table 2 Ecto-enzyme activity and growth rates of cultured glia cells from seizure-prone (DBA) and control (C57) mice

Enzyme	Day(s)	Culture density ($\mu\text{g protein cm}^{-2}$)	Specific enzyme activity* (nmol substrate hydrolysed per mg protein per min)	
			DBA	C57
Ecto-5'-nucleotidase	7	8.2 \pm 0.9	6.54 \pm 0.80 (15)	7.53 \pm 0.41 (9)
	11	12.7 \pm 0.8	5.13 \pm 0.33 (15)	5.41 \pm 0.44 (15)
	18	18.0 \pm 1.1	2.30 \pm 0.20 (15)	2.56 \pm 0.18 (9)
Ecto-ADPase	4	9.0 \pm 1.0	25.1 \pm 1.52 (15)	20.6 \pm 0.64 (15)
p-Nitrophenyl-phosphatase	4	9.0 \pm 1.0	6.30 \pm 0.26 (12)	10.41 \pm 1.37 (15)
			Growth rate†	
—			0.97 (5)	1.24 (5)
—			0.75 (5)	0.70 (5)

Culture conditions were as described in the text and in the legend to Fig. 1. Assay conditions were as for Table 1.

*Values given \pm s.e.m. with number of determinations shown in parentheses.

† $\mu\text{g protein synthesised per cm}^2$ per day.

made at different stages of confluency of the monolayer cultures. Assay conditions are given in Table 1.

When an equal number of D and C cells were plated out, the growth rates (and presumably the viability) of the clones were not significantly different. Both cultures reached about 95% confluency in 11 d. Comparison of the ecto-ATPase activity as a function of cell density revealed a large difference between the two cell lines during the proliferative phases of the cultures (Fig. 1). Ecto-ATPase activity of the glia line derived from seizure-prone DBA mice was significantly lower (Student's *t* test) than that found in C57 glia. On the 7th, 11th and 18th day of culture, D-line glia averaged 35% ($P < 0.001$), 42% ($P < 0.001$) and 86% ($P < 0.3$) respectively of the C-cell controls. During the 7–18 d culture period, ecto-ATPase activity of the C cells had decreased by approximately 35% while that of the D cells had increased nearly 55%. Therefore, on the 18th day of culture, when growth rates were markedly diminished, the ecto-ATPase activity of the epileptic glia line had reached about 85% of that of the controls. This is consistent with the observation that during the later stages of brain maturation in the DBA mouse, the susceptibility of the animal to audiogenic seizures almost vanishes. We have proposed elsewhere that the temporary insufficiency of brain Ca^{2+} -ATPase in the DBA mouse was due to the delayed expression of a more mature ATPase isoenzyme¹. We suggest that this pattern change in ecto-ATPase activity is linked to cell differentiation and (brain) organisation. Although we could not detect organisation in tissue culture, some form of differentiation (for example contact inhibition) may have evoked a similar response pattern in the experiments described here.

Table 2 summarises the values obtained for our presumptive control enzymes. No substantial differences were observed between C57 and DBA glia cells and we assume that the plasma membrane of the DBA glia was normal in other respects. The proposed involvement of glia cells in the genesis of seizures departs from the traditional concept that the epileptogenic lesion ought to be sought in the neuronal elements. Perhaps, because the role of glia in modulating neuronal excitability is poorly understood, their importance in central nervous system function has been underestimated. Several experiments have suggested, however, that neuronal excitability might be mediated by the glia, for instance, by limiting extracellular build-up of substances which might trigger synaptic transmission¹¹. A similar interpretation was made when it was found that neuroleptic drug binding increased with the enrichment of glia cell membranes in brain homogenate fractions¹². Our results do not preclude the existence of neuronal dysfunction in seizure-prone animals, but they strongly suggest that a glial abnormality is implicated in convulsive disorders.

Thus we have shown a deficiency of Ca^{2+} -ATPase, previously demonstrated in seizure-prone animals, to be amplified in the experimental system described here. The ATPase incompetency observed in membrane-enriched homogenates was associated with a lesion in the ectoenzyme activity of the plasma

membrane, and the observed metabolic error (or genetic variant) is a property of the glial elements of the brain (and possibly confined to astrocytes). Our results suggest that a key to the metabolic error in convulsive diseases may be found in the modulating action of ATP on membrane excitability thresholds and the interrelated functions of plasma membrane ectoenzymes.

D-Glucose inhibits potassium efflux from pancreatic islet cells

ELECTROPHYSIOLOGICAL experiments have shown that D-glucose, the major physiological stimulus of insulin release, produces depolarisation and electrical activity in pancreatic beta cells¹ and that a correlation exists between these electrical changes and the stimulation of insulin release^{2–4}. Continuous recordings from single beta cells have permitted characterisation of the regular burst pattern of glucose-induced electrical activity⁵; however, the ionic mechanisms underlying these electrical changes remain unclear and both active and passive ionic fluxes may be involved^{6,7}. Islets incubated in a medium containing a very high glucose concentration (20 mM) retain more $^{86}\text{Rb}^{+}$ than do islets incubated in the presence of 3 mM glucose; this suggests⁸ that the depolarising effects of D-glucose on beta cells might be mediated, at least in part, by a decrease in K^{+} permeability. Recent experiments further showed that tetraethylammonium, a specific blocker of K^{+} conductance, potentiated the effect of glucose on both the inhibition of $^{86}\text{Rb}^{+}$ efflux and stimulation of insulin release from isolated islets⁹. The purpose of the study described here was to obtain direct evidence for an effect of glucose on potassium efflux from pancreatic islet cells and, by comparing the characteristics of this effect with the changes in insulin release and

electrical activity, gain further insight into the ionic mechanisms involved in the glucose control of the secretory function of the pancreatic beta cells. It will be shown that physiological concentrations of D-glucose, but not of L-glucose, markedly modify K^+ permeability in islet cells, that this effect requires D-

Fig. 1 Effect of D-glucose on potassium efflux (a), and insulin release (b) from perfused rat islets. The perfusate contained 3 mM D-glucose (G) except between min 40 to 70, during which D-glucose was either omitted (\circ) or raised to 9 mM (\bullet). In a, the stippled line represents control experiments in 3 mM D-glucose throughout. Values are means \pm s.e.m. of 5 experiments. Isolated islets were obtained after collagenase digestion¹¹ of the pancreas of fed male Wistar rats (275–325 g). All experiments were performed at 37 °C with a Krebs–Ringer bicarbonate solution, pH 7.4, containing 6 mM K^+ , supplemented with 0.5% (w/v) bovine serum albumin and equilibrated with $O_2:CO_2$ (94:6). The perfusion system was similar to that previously described¹⁰, but with a smaller chamber (0.3 ml) and a reduced flow rate (1.1 ml min⁻¹). The dead time of the system is 1 min, but no correction was made in the presentation of the results. Effluent fractions were collected at 2-min intervals except for 1-min intervals from min 40 to 46. In efflux experiments, groups of 75–100 islets were first incubated at 37 °C for 150 min, in 1 ml medium containing 3 mM D-glucose and 6 mM ^{42}KCl (IRE, Fleurus, Belgium; 3.5–6.5 mCi mmol⁻¹). They were then washed three times with 5 ml nonradioactive medium at room temperature and transferred to the perfusion chambers. $^{42}K^+$ in the effluent fractions and remaining in the islets at the end of the experiments was counted in a liquid scintillation spectrometer by the Cerenkov radiation, after addition to each sample of 10 ml of a 3-mM aqueous solution of the wavelength shifter 7-amino-1, 3-naphthalene-disulphonic acid¹². After correction for decay, the fractional efflux of $^{42}K^+$ released during the time interval/ $^{42}K^+$ remaining in tissue during that time interval) was calculated for each collection interval. In release experiments, groups of 15 islets were first incubated at 37 °C for 150 min in 1 ml medium containing 3 mM D-glucose and then transferred into the perfusion chambers. Immuno-reactive insulin (IRI) was measured in the effluent fractions by a double antibody method¹³ with rat insulin as standard.

glucose phosphorylation but is not the consequence of insulin release and, finally, that this change in K^+ permeability may account for the initial depolarising effect of the sugar on beta cells.

A perfusion system^{9,10} was used to monitor continuously the dynamics of $^{42}K^+$ efflux from preloaded isolated rat islets. At concentrations of D-glucose below 5 mM, the efflux of $^{42}K^+$ did not follow simple exponential kinetics, as illustrated by the progressive decrease in the $^{42}K^+$ fractional efflux recorded in the continuous presence of 3 mM D-glucose (Fig. 1a). Withdrawal and subsequent reintroduction of the sugar were followed by prompt augmentation and reduction in the efflux rate. An increase of D-glucose to 9 mM markedly diminished and also stabilised the fractional rate of $^{42}K^+$ efflux (Fig. 1a); this effect of high D-glucose was completely reversible on return to the lower concentration of 3 mM. The concomitant changes in insulin release are shown in Fig. 1b. Omission of glucose did not change the basal rate of secretion, whereas stimulation with 9 mM D-glucose elicited the typical biphasic increase in insulin secretion. It should be noted that the first changes in efflux rate and in insulin release were recorded at the same time (3 min after the switch of the stopcock), but that only the changes in release exhibited biphasic kinetics.

The specificity of this effect of D-glucose was tested by comparison with its non-insulinotropic, non-metabolised¹⁴ stereoisomer L-glucose, which does not produce electrical changes in beta cells⁷. In three experiments (not shown), 6 mM L-glucose was added to a perfusate containing 3 mM D-glucose without significantly changing the rate of $^{42}K^+$ efflux as compared with controls maintained in 3 mM D-glucose alone.

The requirement of extracellular calcium for glucose stimulation of insulin release has long been established¹⁵. Figure 2

Fig. 2 Effects of the absence of calcium (\bullet) or of the presence of mannoheptulose (MH) (\circ) on D-glucose induced inhibition of $^{42}K^+$ efflux from perfused rat islets. After incubation with $^{42}K^+$ as described in the legend to Fig. 1, the islets were transferred to the perfusion chambers and effluent fractions were collected at 2-min intervals. D-glucose concentration of the perfusate was 3 mM from the start of the efflux and raised to 9 mM from min 40 onwards. In one series of experiments (\bullet), Ca^{2+} was omitted from the medium from min 0 to 60 (total $Ca^{2+} < 25 \mu M$) and added to the medium (2.5 mM) from min 60 to 90. In the other series of experiments (\circ), 9 mM mannoheptulose was added to the perfusate during the first 20 min of stimulation with 9 mM D-glucose (min 40 to 60). The stippled line represents control experiments in the presence of 2.5 mM Ca^{2+} and 3 mM D-glucose throughout. Values are means \pm s.e.m. of four experiments.

Fig. 3 Effect of different D-glucose concentrations on $^{42}\text{K}^+$ fractional efflux (●) and immunoreactive insulin release (○) from perfused rat islets. After incubation with $^{42}\text{K}^+$ as described in the legend to Fig. 1, the islets were transferred to the perfusion chambers. The fractional release of $^{42}\text{K}^+$ was measured in identical conditions at all concentrations of D-glucose. Each experiment consisted of an initial period of 36 min in the presence of 3 mM D-glucose and a final period of 28 min in the presence of only one of the various glucose concentrations studied. Effluent fractions were collected at 4-min intervals and the fractional release of $^{42}\text{K}^+$ for individual experiments was defined as the average value for the last 16 min of efflux. Values are means \pm s.e.m. of four experiments. The rate of insulin (IRI) release was studied in a similar manner except that in each experiment four alternate D-glucose concentrations were studied in sequence (starting with the lowest concentration). Values are means \pm s.e.m. of six experiments.

shows that the absence of calcium in the medium did not prevent 9 mM D-glucose from reducing the fractional efflux of $^{42}\text{K}^+$ from preloaded islets and thus demonstrates that the changes in efflux are not a mere consequence of the changes in release. Calcium introduction at 9 mM D-glucose elicited a small and very transient increase in K^+ efflux.

Mannoheptulose, which inhibits glucose phosphorylation in pancreatic islets and glucose stimulation of insulin release¹⁴, reversibly prevented the D-glucose-induced reduction in K^+ efflux (Fig. 2). This observation may indicate that glucose has to be metabolised by islet cells to reduce their permeability to K^+ and is in keeping with the report⁷ that mannoheptulose prevents glucose-induced electrical changes in beta cells.

The relationship between D-glucose concentration and the fractional efflux of $^{42}\text{K}^+$ or the rate of insulin release is shown in Fig. 3. The dose-response relationship for secretion displayed the well established sigmoid shape, with a threshold between 4.5 and 6 mM and a half-maximal response around 9 mM D-glucose. In contrast, the major reduction in K^+ efflux rate occurred at low glucose concentrations, below the threshold for stimulation of release. Above 6 mM D-glucose, only minor further changes in efflux rate were recorded, whereas the rate of release increased considerably. The similarity of the glucose dependency curves of glucose metabolism and insulin release has often been reported¹⁴. This does not necessarily imply that the important changes in K^+ permeability observed at the low glucose concentrations are unrelated to glucose metabolism. Thus, the changes in the overall glucose metabolism may not be exactly representative of the changes occurring at all the successive steps of its metabolism; furthermore, it has been recently reported that glucose utilisation and lactate formation

by islets perfused in a system analogous to that used in this study markedly increased at glucose levels which do not stimulate insulin release¹⁵.

Although K^+ efflux was measured from a heterogeneous population of cells, of which beta cells represent only two-thirds, an instructive comparison can be made with electrical recordings obtained directly in beta cells. When glucose is increased to a stimulatory concentration, the membrane potential first decreases and then starts to oscillate in slow waves (bursts) between a depolarised plateau, on to which fast spikes are superimposed, and a more polarised silent level⁶. The duration of the bursts and the frequency of the spikes are both strongly correlated with insulin release and exhibit the same sigmoidal increase as a function of glucose concentration, with a threshold at 5 to 6 mM⁵. In contrast, the membrane potential between the bursts is glucose independent above that threshold. That K^+ permeability diminishes most markedly for changes between 0 and 6 mM D-glucose suggests that the depolarisation between the resting membrane potential and the threshold potential⁵ at which the burst activity (and insulin release) starts is due to the reduction of the beta cell membrane permeability for K^+ . Once the beta cells are sufficiently depolarised, a Ca^{2+} system (as suggested by disappearance of burst and spike activity after Ca^{2+} removal or addition of the Ca^{2+} antagonist, D 600)^{4,7,17} can be activated. The repolarisation at the end of each burst has, tentatively, been explained either by inactivation of the Ca^{2+} transport system or by activation of an electrogenic Na pump^{6,7}. It is also possible that the duration of the bursts (and the magnitude of the concomitant insulin release) is partially controlled by the K^+ permeability of beta cells. This is supported by the further, although small, reduction in K^+ efflux at suprathreshold concentrations of glucose and by the potentiation of insulin release by tetraethylammonium⁶.

Distribution of Na^+ pump sites in the frog gallbladder

THE energy-dependent transport of fluid across epithelia has been best explained by the three-compartment conception of Curran and MacIntosh¹. This model couples the active 'pumping' of solute with the elaboration of an absorbate of specific tonicity by postulation of local osmosis within the epithelium. This reasoning has been extended in the 'standing-gradient' hypothesis², which accounts for isotonic or hypertonic fluid transport by means of epithelial geometry and the specific transport properties of the cell mem-

Fig. 1 Radioautograph of the frog gallbladder exposed to 1 μ M 3 H-ouabain for one hour followed by a 30-min wash period in cold, ouabain-free Ringer's solution. Grains, indicating 3 H-ouabain binding sites, are distributed on the lateral membranes along the whole length of the intercellular space. Note the large number of grains located at the base of the epithelial cells, especially in comparison to the number located near the junctional region between the cells ($\times 1,440$).

brane. The hypothesis depends upon a quantitative assessment of several parameters (membrane hydraulic conductivity, solute-pump distribution and dimensions of epithelial intercellular spaces)³. For example, the model best explains isotonic reabsorption by the gallbladder when it is assumed that the solute-input region (the site of energy-dependent Na^+ pumping) is confined to the apical portion of the lateral intercellular space². To test this important assumption, we studied the distribution of Na^+ pumps in frog gallbladders with radioautography of 3 H-ouabain binding sites³. This is a specific procedure for identifying the site of the enzyme, $\text{Na}^+ \text{--} \text{K}^+$ ATPase^{6,7}, which in this tissue⁴, as well as others, is equated with the Na^+ pump. We find that Na^+ pumps are present only on the basal-lateral surface of the epithelial cells, consistent with their providing solute to the intercellular spaces as the site for local osmosis. However, since the pumps are not limited to the apical portion of the intercellular space, the results do not support the 'standing-gradient' view of isotonic fluid transport.

Gallbladders of the bullfrog, *Rana catesbeiana*, were

dissected free and washed in Na^+ -Ringer's solution⁸ to remove the bile salts. Then the bladders were divided into small pieces (approximately 5–10 mg) and incubated in Ringer's solution in a shaking water bath at room temperature. 3 H-ouabain was added at a final concentration of 1 μ M and the incubation continued for one hour. This concentration was chosen because it is below the level at which nonspecific binding becomes a major factor⁸. At the end of the incubation period, the vials containing the tissue were drained and refilled with ice cold, ouabain-free Ringer's solution and placed in an ice bath. The medium was changed twice more at 10-min intervals and then the tissue was either quickly blotted and placed in previously weighed vials for wet weight determination or frozen in liquid freon cooled by liquid nitrogen. Frozen pieces of bladder were freeze-dried, fixed and embedded as previously described⁷ except that the tissue was exposed to osmium vapours for three hours to ensure adequate fixation. Sections (1 μ m) were dried on glass slides, dipped in NTB-2 emulsion (Eastman Kodak) and exposed for 1–6 weeks at 4 $^\circ\text{C}$. Quantitative analysis of the grain distribution in each gallbladder was accomplished by a computer-assisted routine similar to the techniques of Mills *et al.*⁷. Hard copies of radioautographs were taped onto a 'spark-pen' data tablet which was serially interfaced to a PDP 11/10 computer and a Princeton 801 graphics terminal. Positional information (the *x-y* coordinates of field boundaries and grains) was input to the terminal and the computer when the spark-pen was touched to the hard copy overlying the sensitised screen of the data tablet. For each field counted, the epithelial thickness was divided into 10 equal slices beginning at the mucosal border and ending at the basal lamina. In this way, the location of each grain was recorded as its relationship to each slice. The final data were then reported as a histogram of the frequency of grains in each slice.

Figure 1 is a radioautograph of a gallbladder exposed to 3 H-ouabain. Exposed silver grains representing 3 H-ouabain binding sites are associated with the entire length of the intercellular space. The most striking observation is that there is no concentration of grains at the apical end of the intercellular space, as might be predicted, while a large number of grains are preferentially located in the basal one-third of the epithelium. A summary of the grain distribution in gallbladders treated as in Fig. 1 is shown in Table 1. The frequency of grains is fairly uniform for slices 1–7. Slices 8, 9 and 10 show a stepwise increase in the number of grains, with slice 10 having twice as many grains as would be expected for an even distribution.

The observed distribution of grains, representing Na^+ pump sites, may have been due to the inability of 3 H-ouabain to reach the apical end of the intercellular space. This is probably not the case, as increasing the incubation time to two hours, or raising the concentration to 5 μ M, had no apparent effect on the distribution of binding sites. In addition, uptake measurements showed that ^{14}C -inulin reached equilibrium in 10 min, while 3 H-ouabain reached an equilibrium binding value in 15 min. Therefore, the localisation of grains along the lateral intercellular space of the gallbladder is presumed to reflect accurately the distribution of Na^+ pump sites along the whole length of the plasma membrane bordering the space. The concentration of pump

Table 1 Distribution of 3 H-ouabain binding sites in the frog gallbladder

Distribution is represented as the percentage of grains (\pm s.e.m.) in each of 10 slices of equal cross-sectional area. Slice 1 begins at the mucosal border and slice 10 ends at the basal lamina. All values corrected for background. (*n* = 5).

sites at the basal end of the cell may be due to the membrane amplification which occurs there⁸; the distribution of pumps may, in fact, be uniform with respect to membrane surface area.

The standing gradient theory would be favoured by a pump distribution which restricted solute input to the apical portion of the intercellular space (the 'dead' end of the channel)¹². Our results, however, indicate that the solute input region is distributed along the entire length of the lateral intercellular space of the gallbladder. This observation, as anticipated and discussed by Diamond and Bossert², does not disprove the standing-gradient hypothesis, but requires the use of extreme values for some of the other important parameters in the model. Isotonicity could still be achieved with a uniform pump distribution if the water permeability of the plasma membranes lining the space was increased upwards. Hill¹⁰, however, has argued that even if the solute pumping region is confined to the upper 10% of the channel length, the osmotic permeability would have to be 3 to 4 orders of magnitude greater than that which has been measured in order to predict an isotonic absorbate by the Segel equation¹¹ for the standing-gradient model. Thus, while the localisation of Na⁺ pumps in the frog gallbladder, as reported here, does not disprove the standing-gradient osmotic flow model, it contributes significantly to the growing body of thought¹² that an alternative explanation for the tonicity of absorbed fluids must be sought.

Sequences and efficiencies of proposed mRNA terminators

THE base sequences at the 3' end of the different messenger RNA molecules show a pattern of a GC-rich region followed by five to eight Us (refs 1,2). Gilbert's hypothesis¹ that the stability of the template duplex DNA (or of the mRNA–DNA hybrid, or both) determines termination of transcription, implies that the DNA termination sequences, and thus the mRNA sequences at the 3' end, are not unique. Rather, the DNA sequence of the template presumably expresses a certain structural stability, and this pattern of stabilities is responsible for the termination of

transcription. Using these ideas we have found five (but only five) sequences in Φ X174 DNA which have a common pattern of stabilities with previous terminator sequences. These sequences are proposed to be responsible for termination of transcription in Φ X174. Three of the five sequences have five or six As following a GC region instead of the Ts present in known terminators. The lengths of mRNAs predicted on this basis are in excellent agreement with published observations; however, sequence determination of the messengers will be necessary to test our proposal rigorously.

We have analysed those termination sequences given by Gilbert in terms of free energy of formation of each of the Watson–Crick nearest-neighbour sequences. There are some data available from thermodynamic studies of synthetic deoxypolynucleotides³, but we have used the complete set of free energy values determined for RNA double strands⁴. The relative stabilities are

GG > GC > CG > AG ~ TG ~ AC ~ TC > AT ~ TA > AA

For simplicity in representing the sequence in these terms, the nearest neighbours are labelled from 1 to 6 in order of decreasing stability. Note that these numbers characterise a sequence of two base pairs, not a single base pair. For example, GC represents the sequence

The known termination sequences^{1,2} are characterised by a most stable nearest neighbour (GG) followed by two variable terms, then a series of weak nearest neighbours such that at least five of seven of the subsequent terms are 6 on the stability scale. Known termination sequences contain oligo U sequences, but we propose that oligo A sequences are also possible; it is the stability of the oligo dA–dT region which is important.

An analysis of the sequence of the plus strand of Φ X174 DNA (ref. 5) reveals only five locations where this pattern of nearest neighbour stabilities occurs (Fig. 1). There are three promoters^{6,7} *in vitro* and the exact location of these has been determined by Sanger⁵. Using these three known mRNA initiation sites and our five proposed termination sequences, the expected mRNAs may be listed according to their molecular weights and which protein codes they contain. A comparison between this prediction and the mRNA found *in vivo*⁸ is given in Table 1. In general, excellent agreement is found.

Hayashi *et al.*⁸ separated fourteen peaks of different molecular weight mRNAs by electrophoresis. By hybridisation of these fractions with restriction fragments, those authors were able to orient nine mRNA fractions on the Φ X174 genome. All were accounted for by predicted mRNAs; seven showed exact agreement in both size and content (fractions 0 and IX are less certain).

Hayashi *et al.*⁸ reported that RNAs starting at promoter A' are rapidly degraded *in vivo*, with the possible exception of RNA species I. In Table 1, the predicted RNAs which do not have counterparts *in vivo* are those that initiate at promoter A'; and the observed fractions *in vivo* which do not correspond to predicted messengers are of smaller molecular weight and thus may represent degradation products.

Of particular significance is the observation that for each of four predicted terminators, one or more observed mRNA fractions may be assigned. No additional terminators need be proposed to explain the observed data. None of the predicted mRNAs which are terminated by T₁ is observed experimentally; therefore, they are not shown in Table 1. Since T₁ differs from the other predicted terminators by the presence of a guanine residue interrupting the AT-rich region, and thus contributing two stronger stability terms, it may be expected to be a less efficient terminator. Axelrod⁷, however, has observed a rho-dependent terminator *in vitro* which maps at a location in agreement with our predicted T₁.

Terminator [*]	Position [†]	Sequence and Stability Terms

Fig. 1 Proposed terminator sequences and stability terms for ΦX174. The approximate location of the last residue transcribed is before the right-hand solid line, except for terminator T_H (indicated by the dashed line).
* Notation from ref. 7; T_G and T_H refer to terminators labelled "start of gene G" and "start of gene H", respectively. † Indicates location of first base listed, using numbering of ref. 5.

Since Hayashi *et al.*⁸ have given values for the relative number of molecules of each of the fractions mapped, the efficiencies of each predicted terminator may be calculated. This calculation uses only those fractions assigned to starts at promoter A. The results in Table 2 are consistent with Axelrod's *in vitro* observations of their primary sequence. The terminator sequences are listed in order of decreasing efficiency in Fig. 1. All terminators require a strong nearest-neighbour interaction, outlined in the box at the left. The other boxed region is composed of ten nucleotides. The efficiency of termination seems to be correlated with the number

vation that T₄ is a strong terminator, whereas T₂ is less effective. In addition, the terminator designated T_H is seen to have a similar efficiency to T₂, and T_G is even less effective.
The relative efficiencies of the terminators may be related to

of adjacent T or A residues and their distance from the strong nearest-neighbour interaction. Thus, T₆ starting in the first position outlined is more efficient than A₆ in the same place or T₆ starting further to the right. All of these are more efficient than A₅

starting in the first position. Given our assumptions about the importance of weak nearest-neighbour interactions in this region, it seems reasonable to speculate that the presence of G after A₅ in T₁ may make this a much weaker, or totally ineffective, terminator. Yet in view of the *in vitro* evidence, this may act effectively in the presence of rho factor. There is obviously still much to be learned about terminator efficiency and sequence, but here we stress the importance of duplex stability (DNA-DNA and DNA-RNA).

On the basis of terminator efficiencies calculated from promoter A, the relative number of molecules for each terminator for another promoter can be calculated, given the assignment of any one mRNA for that promoter. Thus for promoter G, the distribution of RNAs may be calculated given the assignment of RNA XIII to T₂. Good agreement is found for fraction O and III, but one finds that fraction VI contains nearly twice as many molecules as expected. This may be explained by reference to Table 1, where it is seen that two mRNAs of the same molecular weight, but arising from different promoters and terminators, have probably been collected together as fraction VI. Determination of the base sequences of the mRNAs can verify the proposed terminators.

Direct proton exchange between complementary nucleic acid bases

SPECIFIC interaction between complementary nucleic acid bases, in which adenine forms strong hydrogen bonds specifically with thymine (uracil) and guanine with cytosine, is believed to be the molecular basis for the transfer of genetic information. Infrared spectroscopy and nuclear magnetic resonance have shown that such specific interaction is intrinsic to nucleic acid bases¹⁻⁵. In spite of much knowledge about the static structure of the interaction⁶⁻⁹, little is known about the dynamic property of the base pairs. We report here quantitative evidence of direct proton exchange between complementary nucleic acid base derivatives.

9-Ethyladenine (9EA) and 1-cyclohexyl-5-bromouracil (5BrU) can form dimers in chloroform solution¹⁰. Proton magnetic resonance spectra of a 9EA-5BrU (1:1) mixture are shown in Fig. 1. When the amino proton signal of 9EA was irradiated, the imino proton signal of 5BrU disappeared. Similarly irradiation at the imino proton of 5BrU reduced

Fig. 1 ¹H NMR spectra of a mixture of 9-ethyladenine and 1-cyclohexyl-5-bromouracil (both at 0.2 M) in chloroform. *a*, Irradiated at the position where is no signal. *b*, Irradiated at the amino proton of 9-ethyladenine. *c*, Irradiated at the imino proton of 1-cyclohexyl-5-bromouracil. Asterisk indicates the irradiated position.

the intensity of the amino proton of 9EA. With dimethylsulphoxide (DMSO) solution of the 9EA-5BrU (1:1) mixture, there was a smaller decrease in peak intensity than with chloroform solution. DMSO more effectively disturbs the formation of solute-solute hydrogen bonds. Thus the observed decrease of the nonirradiated proton signal correlates closely with the quantity of hydrogen bonded dimers between 9EA and 5BrU.

These results can be explained as follows. Protons are reversibly exchanging between the amino group of 9EA and the imino group of 5BrU, and thus the irradiated proton moves to the nonirradiated site through the formation of hydrogen bonded dimers. The exchange of saturated protons produces partial saturation of the nonirradiated proton site to weaken the intensity of the nonirradiated proton resonance, if the exchange rate is faster than the relaxation time^{10,11}. Irradiation at the signal of water proton contaminated in solution gives little change in the intensity of other proton resonances. This suggests that most protons do not exchange by way of the water in the solvents.

The same experiment was performed using a mixture of 9-ethylguanine (9EG) and 1-methylcytosine (1MC) in DMSO. In this system it is interesting that proton exchange occurs between the imino proton of 9EG and the amino proton of 1MC (Fig. 2), but the amino proton of 9EG does not exchange with both the amino proton of 1MC and the imino proton of 9EG (Table 1). If the formation of cyclic hydrogen bonds of the G-C pair^{8,9} is a sufficient condition for the exchange of protons, the amino proton of 9EG should ex-

Table 1 Partial saturation induced by intermolecular exchange of saturated protons

*, 0.2 M.

†, 0.1 M.

change with the other protons participating in hydrogen bonds, in view of the distance between the protons. These results make us consider factors other than distance for the mechanism of intermolecular proton exchange. The proton transfer induced by the imino and enol tautomers¹² or protonated species¹³ can be considered as possible explanations.

For this we shall estimate quantitatively the life time of the proton exchange. We consider the system where the nucleus X exchanges between site A and site B, and the nucleus X in the site B is saturated by irradiation at the A site proton. Forsén and Hoffman's analysis^{9,10} gives 0.1 s as the life time for the proton exchange if we use the data of the spin lattice relaxation times observed separately (0.23 s for A-NH₂). Thus the proton exchanges 10 times in a second for the 9EA-5BrU system in chloroform.

**Fig. 2** Exchangeable protons in the G-C pair.

Here we have used model compounds for nucleosides, and our experiments were carried out only for the monomer systems. In spite of these limitations, there is no reason to deny proton exchange in nucleic acid. The structures of nucleic acid bases which are realised at the time of the proton exchange are different from the normal structures. Although we do not know the real effect of proton exchange in complementary base pairs on biological process, such altered structures might induce mispairing in the replication and transcription of nucleic acids¹⁴.

Relaxin and its structural relationship to insulin

THE sequence of the ovarian peptide, relaxin, has recently been reported^{1,2} and the observation¹ that it can be accommodated into the insulin fold has been discussed^{3,4}. Only 11 residues, including the cystines, are common to insulin and relaxin (Fig. 1), but the probable identity of the cystine pairings and the preservation of the hydrophobic character of buried residues suggests some structural homology between the two hormones. The extent of sequence changes and the remote relationship between the corpus luteum and the pancreas, the respective sources of relaxin and insulin, makes homology of the two hormones most interesting. We have therefore rigorously examined the relaxin conformation by a computer graphics system and found it possible to accommodate the relaxin sequence within the insulin main-chain geometry.

We first considered the packing of residues whose equivalents in insulin are buried or partly buried. We chose molecule 2 of the 2-zinc insulin⁵ structure for the comparison since the conformations in this monomer are most closely related to those of 4-zinc pig insulin⁶ and the dimeric hagfish insulin (Cutfield, J. F. *et al.*, in preparation). The atomic positions of this insulin molecule are now accurately known and for the buried residues the estimated errors are 0.1-0.2 Å. Using Labquip models, we found that the internal hydrophobic residues of insulin could be replaced by the equivalent relaxin residues without the apparent need to adjust the main-chain conformation. In particular, there was an extensive cavity into which tryptophan B₁₅ seemed to fit nicely. Because of the limitations and inaccuracies in model building which we consider might be misleading, we then used a computer graphics system^{7,8} to superimpose the relaxin chains on to the insulin backbone. Any short contacts were indicated immediately by dotted lines between the offending atoms. Side-chain conformation were adjusted by rotations about single bonds until acceptable stereochemistry and packing was achieved. We found that tryptophan B₁₅ can indeed be directed into the relaxin core with no contacts unacceptable in relation to the precision of the insulin coordinates. This and the equivalent insulin structure are shown in Figs 2b and 2a.

Some alternative arrangements of buried side-chains are possible without adjustment of the main chain. An advantage of the computer graphics system is that such alternatives can be rapidly explored. In particular, we found that tryptophan B₁₅ can be orientated in a second distinct way (Fig. 2c) related principally by 180° rotation about the C_β-C_γ bond, and corresponding essentially to that reported by Bedarker *et al.*⁴. It gives a rather more open hydrophobic core than our preferred alternative of Fig. 2b.

We built the terminal stretches of chain beyond the disulphide bridges as they occur in insulin. The additional residues at the N termini were built in arbitrary but sensible conformations giving reasonable contacts to the main body of the molecule. There were two difficulties at the B-chain C-terminus. The sequence reported by Schwabe *et al.*² differs from that of

Fig. 1 a, The amino acid sequences of insulin and relaxin; **b**, the insulin main chain viewed from a direction that illustrates the relative positioning of the central B-chain α helix and the two roughly antiparallel A-chain helical stretches. The hydrogen bonds in the well defined B-chain α helix and subsequent turn are dotted; we expect this structural element to be least affected by the sequence changes in relaxin. *, Residues which seem to be crucial to the integrity of the insulin structure and which differ in relaxin. The extensions at the N termini in relaxin relative to insulin are represented as ribbons, the deletions at the C termini by dashed lines.

James *et al.*¹ from B₂₁ onwards, possibly because of microheterogeneity. (This does not affect the central region of the molecule.) We have followed the sequence of James *et al.* and for simplicity identify relaxin residues by their position in insulin. In insulin, B₂₃ is glycine and its substitution by an L-amino acid (serine in the sequences of James *et al.*, valine in that of Schwabe *et al.*) would give impossible contacts, so there must be a conformational difference here between relaxin and insulin. We continued beyond B₂₃ in a way which left the residues near the positions of their equivalents in insulin. In contrast to B₂₃, the glycines at B₈ and B₂₀ are preserved in relaxin.

The main features of our proposed model are: (1) of the two tryptophans, B₁₅ is buried while B₂₅ is exposed. This fits the chemical and fluorescence observations of Schwabe and Braddon⁹, who found that one tryptophan reacted readily without altering the hormone's potency, while reaction of the second was very difficult and inactivated the hormone; (2) there are compensating changes in side chains that are spatially related, such as B₆ and B₁₄ and A₂ and A₁₆, which are consistent with insulin and relaxin having the same internal organisation¹¹ (see Fig. 1a); (3) there is complementary distribution of the many charged side chains, particularly noticeable on the helical stretches. This not only supports the proposed folding but also suggests that the relaxin molecule achieves stability as a monomer through these favourable interactions¹⁰; (4) detailed changes near B₂₃ modify the characteristics of the monomer surface involved in dimer formation in insulin; (5) residues B₉ to B₁₉ fit well in an unbroken α helix, so that the

Fig. 2 Buried residues in the central core: *a*, 2-zinc insulin; *b* and *c*, alternative arrangements of Trp B₁₅ in relaxin. The A chain is shown by open bonds and the B-chain by solid bonds.

Fig. 3 A stereo view of the complete relaxin molecule with B₁₅ as in Fig. 2*b*.

improvement in sequence homology achieved by displacing the two sequences at B₁₄ to B₁₇ (ref. 1) seems to have no significance in structural terms.

We consider that relaxin has a three-dimensional organisation similar to that of insulin. We do not yet know the closeness of this relationship but note that insulin itself shows considerable structural variation⁶. Thus, while the B-chain α helix is closely preserved, we find widely different conformations of the terminal residues and some alterations of the A-chain helical structure. Therefore, we might expect greatest similarity between relaxin and insulin in the α -helical B-chain and increasing differences in the A chain and the chain termini.

Amongst the many sequence differences between insulin and relaxin, there are two of particular relevance to function. The first is the absence of residue A₂₁ in relaxin. When A₂₁ asparagine is removed from insulin so that, like relaxin, its A-chain terminates at A₂₀ cystine, the hormone's solution and spectral properties are profoundly altered¹¹, its A-chain is apparently perturbed¹² and its biological potency is much reduced^{11,14}. Second, the substitution of B₂₃ glycine by an L-amino acid has been shown by the Chinese studies effectively to abolish insulin's biological activity¹⁵. In diverging from insulin at A₂₁ and B₂₃, relaxin therefore will be without the capacity to behave like insulin. (We note that in the insulin-like peptide responsible for the non-suppressible insulin-like activity in the serum (insulin-like growth factor), B₂₃ is glycine and A₂₁ is alanine, though this is not the C-terminal amino acid¹⁶).

X-ray analysis of relaxin and other hormones with recognised homology to insulin¹⁷ could clarify the relationships between their sequences, structures and biological behaviour.

We thank Professor T. L. Blundell for showing us the paper by Bedarkar *et al.* before publication. The coordinates of our model have been deposited with the Protein Data Bank.

A novel continuous sequence of 41 aspartic and glutamic residues in a non-histone chromosomal protein

THE structural functions of four of the five histones are now partially understood¹ and the nucleosome structure of chromatin well established^{2–4}. However, superimposed on this basic nucleosome structure is some heterogeneity with respect to the other chromosomal proteins, since although it has been shown that isolated nucleosomes contain non-histone chromosomal proteins^{5,6}, there are insufficient of some classes for one per nucleosome. These nucleosomal non-histone chromosomal proteins have been designated the high-mobility group (HMG) proteins. They have been fractionated, and the main components, HMG 1, HMG 2, HMG 14 and HMG 17 have been isolated in a pure form^{7–9}. The complete amino acid sequence of one of these proteins, HMG 17, has been determined¹⁰. We report here that the C-terminal region of protein HMG 1 contains an extremely unusual sequence of amino acids—41 aspartic and glutamic acid residues.

The molecular weight of HMG 1 as determined by sedimentation equilibrium, is approximately 26,000. One of the interesting features of HMG 1 is the fact that over 50% of its amino acid residues are charged. Like the histones, 25% of the residues are basic. However, unlike the histones this protein also contains 30% acidic amino acids. Because of the quantities present in the nucleus (approximately 10⁶ molecules), we feel that, like the histones, HMG 1 is a structural protein and is probably not involved in specific gene control.

Previous work has shown that the acidic amino acids in HMG 1 are irregularly distributed within the molecule¹¹. A cyanogen bromide peptide, CB2, approximately 120 amino acid residues in length, has been isolated from HMG 1 (ref. 11). This peptide contains 47% aspartic and glutamic residues, and because of the absence of homoserine or homoserine lactone presumably comes from the C terminal of HMG 1. The sequence of the first 44 residues of this peptide has been determined on a protein sequenator (unpublished results). As this sequence contains only 10 aspartic and glutamic residues (23%), the majority of the aspartic and glutamic residues must, therefore, be concentrated in the C-terminal portion of this peptide. We present here evidence that the aspartic and glutamic residues in the C-terminal region of this peptide are, in fact, present as a region of 41 aspartic and glutamic acid residues in continuous sequence.

The elution profile of a tryptic digest of peptide CB2 on a Sephadex G-25 column is shown in Fig. 1. The elution profile shows a peak (T) which elutes just within the excluded volume of the column. This peak was further purified by descending chromatography on Whatman 3MM paper in butanol–pyridine–acetic acid–water (90 : 60 : 18 : 72) for 7 d. A single peptide (T1) moved about 1 cm from the origin leaving a small amount of ninhydrin-positive material at the origin. This peptide (T1) was eluted with 5% acetic acid and lyophilised. The amino acid composition of peptide T1 was determined as Lys₃, Asx₁₂, Glx₂₆ and the N-terminal amino acid shown to be lysine by dansylation. The amino terminal sequence of this peptide was determined on a protein sequenator and was shown to be Lys-Lys-Glu-Glu-Glu-Glu-Asp-Glu-Glu-Asp-Asp-Glu. As this peptide was produced by tryptic cleavage of CB2, a lysine residue would be expected at the C terminal of this pep-

Fig. 1 Sephadex G-25 (90 × 2.4 cm) elution profile of the tryptic digest of CB2. For the digest, peptide CB2 was dissolved in 0.2 M ammonium bicarbonate (10 mg ml⁻¹) and incubated at 37 °C at an enzyme to peptide ratio of 1 : 50 (w/w) for 4 h. The digest was lyophilised and run in the column in 0.01 M HCl: 5 ml fractions were collected.

tide. This peptide could not end at the C terminal of HMG 1 as we have previously shown the C-terminal sequence of HMG 1 to be Phe-Ala-Lys¹². It therefore seems, from the amino acid composition of peptide T1, that we have a continuous sequence of 41 aspartic and glutamic residues with a lysine residue at each end. This peptide was taken through 25 cycles on the sequenator, and although unambiguous identification of the sequence beyond step 12 was not possible, no asparagine or glutamine residues were observed on any of the cycles. Additionally, it is unlikely that any of the aspartic or glutamic residues in this peptide are amidated, since we have previously shown¹² that only about 11 aspartic and glutamic residues are amidated in the total molecule, and we have found this number of amidated residues in other peptides during our sequence studies on this protein. The known difficulty of removing the thiazolinones of aspartic and glutamic acid from the sequenator cup at the butyl chloride wash step presumably contributed to the considerable amount of overlap that was evident by cycle 12. Both aspartic and glutamic acid residues were identified on the later cycles, but it was not possible to determine an unambiguous sequence.

We have previously shown that peptide CB2 does not bind to DNA¹¹, unlike total HMG 1. This is not surprising considering the acidic nature of this peptide. It seems likely, however, that this region will combine with basic parts of other chromosomal proteins and may even compete with the DNA and possibly break down the nucleosome structure. Interference with the DNA-histone interactions, or possibly some form of higher order structure, or cross-linking, would seem the most likely functions for this molecule, considering that there is only sufficient HMG 1 for approximately one in six nucleosomes⁵.

Electron density map of apoferritin at 2.8-Å resolution

THE structure of ferritin is of considerable interest because of its widespread occurrence in higher organisms, signifying a general need to store iron and remove this essential, but toxic element. Horse spleen apoferritin has a molecular weight (MW) of about 444,000 and is composed of 24 subunits (MW 18,500) each containing about 163 amino acids¹. These are arranged in 432 symmetry to form a nearly spherical hollow shell with outside and inside diameters approximately 130 Å and 75 Å respectively¹⁻³. The large cavity inside the molecule can store up to 4,500 Fe atoms, packaged in a microcrystalline inorganic component of approximate composition (FeOOH)₈(FeO:OPO₃H₂) (refs 4-6). The atomic structure of the micro-crystals is not specifically related to the surrounding protein structure⁶. Apoferritin catalyses the oxidation of Fe(II) which it retains inside the molecule as the ferric hydrolysate^{7,8}. Our 6-Å resolution structure of apoferritin⁹ showed the presence of several rods of electron density, tentatively assigned as α helices, and channels passing through the shell, which could provide an access route for Fe atoms. These features have been confirmed at 2.8-Å resolution and we can now also provide a plausible subunit conformation and quaternary structure.

Ferritin was purified from horse spleen and reduced with sodium dithionite at pH 4.8 (ref. 2). Apoferritin crystals (F432, *a* = 184 Å, *Z* = 4) were grown as previously described³. Two heavy atom derivatives used for phase determination were prepared by soaking crystals in 1% CdSO₄ solution containing either *p*-chloromercuribenzoate (PCMB) or K₃UO₂F₅.

Data to 2.8-Å resolution were collected on an Arndt-Wonacott oscillation camera using monochromatised Cu Kα radiation. Heavy atom parameters were refined using full matrix least squares refinement on centric data. Phases for all reflections were calculated by the method of Blow and Crick⁹ using anomalous scattering information¹⁰. The mean figure of merit for the phase set was 0.62. Details of heavy atoms derivatives used are shown in Table 1.

The electron density map, small portions of which are shown in Fig. 1, shows that the subunits are arranged within the

‡Parameter not refined.

Fig. 1 Sections of the 2.8-Å resolution electron density map of horse spleen apoferritin viewed nearly parallel to the fourfold axis. Each part of the map shown comprises sections at intervals of $1/132$ of the unit cell edge, with contours at equal and arbitrary levels. A complete slice through the molecule is obtained by operation of the fourfold symmetry axis. *a*, Eight sections near the centre of the molecule. The molecule is seen as a hollow shell, two layers of helices thick. Two peaks related by a unit cell dyad (dotted line) form a double bridge between neighbouring molecules in the crystal. We attribute these to Cd^{2+} of crystallisation. The full circle near to the twofold axis, but on the inner surface of the shell shows the position found for a Tb^{3+} ion in a separate isomorphous replacement study. *b*, Nine sections near the top of the molecule. The left hand edge of the map cuts through one of the six channels which penetrate the shell along the fourfold axis. The subunits of the shell each comprise four long α helices (some shown in the illustration) and a short helix. The short helices from adjacent subunits surround the channels and can be seen on end. *c*, A complete slice about 100 Å across and 10 Å thick through the apoferritin electron density map near the top of the molecule viewed down a fourfold axis. Scale of (*a*) and (*b*) approximately $1.6 \times$ that of (*c*).

protein shell so as to form a bilayer of α helices enclosing the central cavity (the iron core in ferritin). The helical axes lie perpendicular to the radius vector, hence one layer of helices faces inwards and the other outwards.

Subunits are roughly cylindrical with h about 55 Å and d about 27 Å. The main structural features, accounting for about two-thirds of the primary structure, are four very long α helices (34–42 Å) with their axes nearly parallel, making up most of the cylinder length. There is an additional short length of helix perpendicular to the major helices. We have attempted to trace the complete course of the polypeptide chain in the electron density map and to determine its direction, but in the absence of sequence information, this cannot be done with complete confidence. However, although there are some ambiguities in inter-helical connectivities, which lie at the molecular surfaces, a plausible interpretation is shown in Fig. 2. In this structure the four long helices form two anti-parallel pairs. Helices B and C seem to be connected at their opposite ends by a long, extended loop, such that the pairs of helices are related by a pseudo-dyad perpendicular to their lengths. The short helix, E, probably lies at one of the chain termini.

We have tentatively assigned the N-terminus to the end of a

Fig. 2 Schematic drawing of an apoferritin subunit. The subunit contains four nearly parallel helices 34–42 Å long and a short helix, E, at right angles to these. Four of the short helices, E, line the channels while the long helices lie along the molecular surfaces. Non-helical segments connecting the helices are indicated. These have been derived from the map and provide a plausible subunit construction, although the connectivities cannot as yet be assigned with certainty.

short non-helical segment attached to helix A. The long connecting loop between helices B and C lies over the surface of the apoferritin molecule. Proteolytic attack at this accessible loop could account for the 6,000–8,000 and 10,000–12,000 MW fragments sometimes observed on polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulphate^{11,12}. The tertiary structure of a subunit superficially resembles myohaemerythrin¹³, which also contains two anti-parallel pairs of helices, and the tobacco mosaic virus (TMV) subunit¹⁴, but in TMV subunits pack with their helices lying radially rather than tangentially as in apoferritin.

The packing of subunits into the quaternary structure of apoferritin suggests the formation of stable dimers as intermediates in self-assembly. Subunits related by molecular dyads overlap along most of their length (Fig. 3*a*) with a larger mutual area of contact than those around threefold (Fig. 3*b*) or fourfold axes (Fig. 4*b*). Eight helices in the dimer lie roughly parallel to one another. Contacts between subunits around fourfold axes are relatively tenuous and stable symmetrical tetramers would not be expected (Fig. 4*b*). Operation of the fourfold axis produces approximately 10 Å-wide channels through the protein shell noted at low resolution³ (Fig. 4*a, b*), which are lined by short helices (E in Fig. 2), seen end-on in Fig. 1*b* and *c*.

Around the threefold axis the contact region is greater than at the fourfold. The cylinders form a three-blade propeller arrangement, with one end of the cylinder lying approximately perpendicular to the cylindrical surface of its symmetry-related neighbour (Fig. 3*b*). Formation of hexamers by aggregation of dimers around the trigonal axis might be expected to be a second stage in assembly. The subunit interactions are reminiscent of those in methaemerythrin, where parallel and perpendicular cylinder stacking is also found¹⁶, although the overall symmetry and number of inter-subunit contacts differ. A schematic drawing of the apoferritin quaternary structure viewed down a fourfold axis is shown in Fig. 4*a* in which it can be seen that each subunit is in contact with five neighbours.

Several metal binding sites can be located with respect to the subunit structure. The major PCMB site is near the threefold axis, towards the outside of the molecule. Other sites are near either the molecular or cavity surfaces. No metal ions have been found embedded within the shell either within or between subunits. Pairs of peaks, which we attribute to Cd^{2+} of crystallisation, occur close to the twofold axes on the outside of the molecule and connect adjacent molecules in the crystal

Fig. 3 Schematic views of apoferritin subunits, showing local packing around *a*, molecular twofold axes, *b*, molecular threefold axes. Only helical regions are shown. The helical rods from neighbouring subunits related by molecular dyads overlap along most of their lengths, and give a system of eight nearly parallel rods. A symmetrical dimer is thus suggested as a stable intermediate in the assembly of the protein shell. Probable inter-helical connections suggest that chain directions alternate so that neighbouring helices are antiparallel. Subunits related by molecular threefold axes have their helices nearly perpendicular and there is less inter-subunit contact than around the twofold axes.

(Fig. 1*a*). The Cd^{2+} ion pairs are bound roughly half way along the extended BC loop. Four loops and two Cd^{2+} ions participate in the double intermolecular bridge.

Not used in the structure determination, but found in separate isomorphous replacement studies are Tb^{3+} ions on the inner surface of the shell. The major site (Fig. 1*a*) is close to the twofold axis at a radius of 41.6 Å and only 4.3 Å from its symmetry-related pair. The Tb^{3+} sites which probably involve carboxyl groups¹⁵, are of special relevance to ferritin formation. Our mechanism for the catalytic action of apoferritin in the oxidation of Fe(II) , which gives it the power to accumulate Fe(III) , becoming ferritin, involves sites for Fe(II) -oxidation and heteronucleation of hydrous ferric oxide⁸. Tb^{3+} ions inhibit iron uptake by apoferritin, and may bind at Fe-binding sites.

Fig. 4 Schematic drawings of the subunit arrangement in an apoferritin molecule viewed down a fourfold axis. *a*, Complete molecule showing some of its symmetry axes. *b*, Subunits related by a fourfold axis. Subunits approximate to cylinders or ellipsoids with length (approximately 55 Å) about twice their diameter (approximately 27 Å), although the shell is rather more smooth than these shapes suggest. Each subunit is in contact with five neighbours, although the contacts are of only three different types around the three different symmetry axes (as in Figs 4*b* and 3*a*, and 3*b*). The four major helices present in each subunit have their axes roughly parallel to the long axes of the subunits as drawn schematically in *b*. The interactions between subunits making the symmetrical tetramer seen in *b*, are less extensive than those in the symmetrical dimer and trimer of Fig. 3*a* and *b*. Compare with Fig. 1*c*.

The presence of a double site suggests the possibility of a cooperative two-electron transfer to oxygen from two close Fe(II) , giving two Fe(III) , which is followed by the formation of an oxo-bridge by elimination of protons from bound water molecules. Here again we can compare the structure with that of myohaemerythrin¹³, in which each subunit contains a pair of Fe atoms 3.44 ± 0.05 Å apart, which reversibly binds oxygen. This Fe-Fe pair is set well within the subunit, whereas in apoferritin the Tb^{3+} ions belong to different subunits and lie on the inner surface of the protein shell.

We thank the SRC, MRC and the Royal Society for financial support. We thank Drs H. Watson and H. Muirhead and their colleagues at Bristol for assistance and for providing facilities for X-ray film measurement and processing.

Announcing a New Journal . . .

INVESTIGATIVE AND CELL PATHOLOGY

This Journal is an independent, international periodical which will be published quarterly. It aims to provide a forum for original papers concerned primarily with the correlation of structure and function in normal and pathological tissues.

Within this context, the Journal will cover all aspects of investigative pathology and experimental medicine. Original articles concerned with cell biology, embryology and teratology in relation to human disease will be encouraged. Contributions concerned with animal models of human disease, new techniques, tumour pathology; iatrogenic and metabolic disease will also be included.

Each issue will contain signed editorials on topical or controversial aspects of investigative and cell pathology, together with one or more review articles related to areas of current interest. Letters to the Editor and reviews of recently published books will also become a regular feature of the Journal.

Pulsar compilation

F. Graham Smith

Pulsars. By R. N. Manchester and J. H. Taylor. Pp. 281. (Freeman: San Francisco and Reading, 1977.) \$9.95.

THE ten years since the discovery of the pulsars have seen the publication of a bewildering flood of information on their properties, a plethora of theories about how they work, and a rather more coherent set of papers on their distances, their population within the Galaxy, and on the effects of the interstellar medium on the propagation of their radio pulses. Drs Manchester and Taylor have between them contributed a large proportion of the observational material now available to us, and it is very helpful to find so much assembled in one volume.

The difficulty with the pulsars is that we do not really know how they pulse; more precisely, we do not know how they produce the searchlight beam which crosses our line of sight each time the underlying neutron star rotates. The book cannot therefore start with an exposition of the structure of a pulsar, working from the core of the neutron star outwards, because it would be in difficulty as soon as it left the surface and entered the magnetosphere which is the seat of the observed phenomena. The authors therefore take the course of piling the observations into the first two-thirds of the book, leaving the reader dazzled with a rich assortment of phenomena, and presenting the theories in the remaining third. The theories have turned out to have almost the same richness and variety as the observations themselves. Here is the problem: should the authors select what they regard as the key observations, indicate those theories that can possibly accommodate them, and throw out the theories that now seem impossible? The alternative, which the authors adopt, is to keep an open mind and trust that the reader will be able to do the sorting out for himself. As a consequence, the origin of the pulses moves, from page to page, and even within a page, from near the surface to outside the velocity of light cylinder without much guidance to the reader.

The chapters on the interstellar medium and the population of pulsars are very useful and clear expositions. There are good discussions of the Crab

Nebula, and on the relativistic effects to be expected in observations of the binary pulsar. The chapter on X-ray pulsars is a useful introduction, although the subject grows so rapidly that it is already out of date.

The observational material includes some previously unpublished work, and is up-to-date in including the optical observations of the Vela Pulsar, made in January 1977. This latter work, incidentally, has been inserted into a

chapter on X-ray pulsars and binary systems, neither of which is an appropriate category.

Given that there is as yet no key to unlock the main mystery of the pulsars, this book is welcome as a compilation and an authoritative commentary. There is a good index to help one find one's way around. □

F. Graham Smith is Director of the Royal Greenwich Observatory, Herstmonceux Castle, Sussex, UK.

Protein chemistry for immunologists

Immunochemistry of Proteins. Vols 1 and 2. Edited by M. Z. Atassi. Pp. 438 and 485. (Plenum: New York and London, 1977.) \$53.40 each volume.

THE first volume is a hotch-potch of a book, masquerading under a false title and falling between a definitive work and a collection of contributors' 'pet topics'. Over half of the book is devoted to chapters by the editor himself (M. Z. Atassi) and a colleague (A. F. S. A. Habeeb), on chemical modification and conformational aspects of proteins, respectively. And much of what they say could hardly be considered as immunochemistry according to the accepted meaning of the term. Habeeb does, however, make a few comparisons between the structural and antigenic relationships of proteins of different species of origin, besides offering some reflections about the application of immunochemistry which include the somewhat obvious conclusion that "... advances in immunochemical research in the last two decades resulted from the development of new techniques and methodologies".

The selection of the topics treated by most of the other authors has obviously been on an arbitrary basis. For instance, along with useful contributions on histocompatibility antigens (still very much in the throes of characterisation) and the antigenicity of collagen and encephalitogenic proteins, there is but one chapter dealing with the study of antigen-antibody interaction (by the somewhat specialised fluorescence polarisation technique). There is also a chapter on lymphoid cell responses to protein and peptides. All in all then a 'very mixed

bag' of subjects, of variable immunochemical appeal.

The recent appearance of a second volume in the series has done little to mollify these types of criticism. Again, there are useful practically orientated chapters, such as the one by Parikh and Cuatrecasas on affinity chromatography and other more theoretically inclined ones dealing with topics like "the effect of antigen structure on immunogenicity". There is also a chapter on Concanavalin A.

Over half of this volume, however, is devoted to contributions on the antigenic structures of those proteins which have now been well characterised, that is, myoglobin, lysozyme and tobacco mosaic virus. And, although the major contributions to this field by Atassi and his coworkers serve as valuable models to those engaged in the similar characterisation of other proteins, one cannot help gaining the impression that these two volumes are mainly outlets for wider propagation of such approaches to structural characterisation rather than attempts to provide well balanced texts on immunochemistry. Where, for example, is any treatment of the contribution of the antibody to immunochemical reactions, or of other ancillary proteins like the complement components?

Perhaps such topics will be considered in later volumes. In the meantime, a fairer title of the present two volumes would be *Protein Chemistry for Immunologists*, but even then the coverage is 'uneven' to say the least.

Mathematical conversion kit

Mathematics Applied to Continuum Mechanics. By Lee A. Segel. Pp.xviii +590. (Macmillan: London and New York, 1977.) £14.25.

ALTHOUGH the general tradition of mathematics departments in the US had been rather specialised towards pure mathematics, the best American universities have recognised for many years now the need for Applied Mathematics Programs. These have been aimed, especially, at helping those who, although brought up in the pure mathematics tradition, would like to consider the possibility of transferring their interest to fruitful areas of application of mathematics.

For example, one of the finest and oldest of the world's technological universities, Rensselaer Polytechnic Institute in Troy, New York, has given an introductory applied mathematics course to its mathematics students for ticity theory contributed by G. H. Handelman initiated it. It was later developed by Dr L. A. Segel, whose book *Mathematics Applied to Continuum Mechanics* in 12 chapters (with the material of chapters 4-6 on elasticity theory contributed by G. H. Handelman) has grown out of the course.

Applications of mathematics fall into two main areas. One involves the discernment and utilisation of laws of nature, as illustrated by Dr Segel's book or by its more elementary predecessor *Mathematics Applied to Deterministic Problems in the Natural Sciences* (C. C. Lin and L. A. Segel (Macmillan: London) A contrasting area of application is to statistical treatments of observed regularities and variabilities in systems where no underlying laws are known. Both are of immense practical utility, and it is important that mathematical education should make students aware of both.

In Britain, those taking mathematics in the immediate pre-university years have commonly had that advantage, being exposed both to mechanics and statistics as well as to pure mathematics, and their university course has built on that background and developed considerably within the area of mathematics applied to engineering and the natural sciences, as well as within statistics and operational research. More recently, in gross neglect of the country's needs, many schoolteachers have taken away from students the uniquely valuable example of elementary mechanics as an area illustrating mathematics applied to problems in engineering and the natural sciences, where natural laws are discerned and

utilised. Consequently, students enter university mathematics departments without any knowledge of this great division of applied mathematics, and with an educational background based on pure mathematics with some leavening of statistical distribution theory.

For the first time, then, British universities may be facing the problem which has long existed in the US, and which the best American universities have been seeking to counter with books like those of Dr Segel. Such books, directed rather explicitly at students with a good modern background in pure mathematics, but with little or no idea of classical applied mathematics or the uses of mathematics in engineering science, are aimed at capturing the interest of such students, and at bringing them to begin thinking in ways valuable to such applications.

Exercises abound throughout this excellent book and are effective (with or without use of the 'hints' section at the end) as a major method of exposition of material. Part A gives a good grounding in vector and tensor algebra and calculus, with particularly clear explanations of why all the definitions are appropriate. Part B gives a good introduction to rate-of-strain, viscosity, vorticity and boundary layers; and to strain, elastic constants, energy and uniqueness principles, bending, buckling, torsion, plane strain, generalised plane stress, and elastic waves.

Physical variability of the oceans

Variability of the Oceans. By A. S. Monin, V. M. Kamenkovich and V. G. Kort. Pp.xiii + 241. (Wiley-Interscience: New York and London, 1977.) £14.95; \$25.35.

THIS monograph by three well-known Soviet oceanographers is a survey of the physical variability of the oceans on widely varying space and timescales. Although the writing is clear and the errors few, I suspect that the book will have a limited readership.

The major shortcoming is that the most recent reference to the Western literature is 1973, and only 6% of all Western references are dated after 1970. Soviet citation runs a bit later, as one would expect. As any casual observer of physical oceanography will have noticed, ocean variability has probably been the area of greatest advance since 1970, and understanding of many parts of the spectrum has improved markedly since then. Furthermore, oceanography is a very technologically dependent subject, and it is in technology that the Soviet Union most obviously lags

Part C, on water waves, is concerned mainly with the deep-water case. There is a good introduction to group velocity. For example, the crest pattern is found not only for gravity waves generated by a large obstacle in steady motion (ship waves) but also for the limiting case of a very small obstacle making capillary waves. The author calls these 'beetle waves' in reference to a pretty frontispiece photograph! Part C concludes with a brief but interesting treatment of second-order effects. For me, only its opening chapter, deriving the free-surface condition and other basic equations, seemed to me to adopt an unnecessarily cumbersome approach based on excessive adherence to 'scaling' doctrines.

Finally, Part D is concerned with setting out the calculus of variations and its important applications in mechanics, and continues the excellent practice of getting the reader to work out the details in most of the really interesting examples. Wherever universities are faced with 'converting' students grounded primarily in pure mathematics to the great variety of its exciting and important applications in the mechanics of solids and the mechanics of fluids, I believe that they will find this book a most valuable conversion kit.

James Lighthill

Sir James Lighthill is Lucasian Professor of Applied Mathematics at the University of Cambridge, UK.

behind the West. Thus the more recent Soviet references do not make up for the dated discussion of Western work to the extent that one might otherwise have expected. The commonly remarked Soviet strength in theory does not compensate in this field for their missing observational strength, but does lend a formal tone to much of the book.

A good textbook need not be fully modern, and oceanography painfully lacks such textbooks. Students trying to enter oceanography, however, will find the subject matter here too terse. For those already conversant with the field, the obsolescence will be a serious defect. Perhaps the book is best used as an annotated bibliography of material through 1970. It also has historical value, as it provides insight into the thinking of some of the most prominent Soviet oceanographers in the early 1970s. In many ways, the book reads like the type of overall summary of a field that has become a commonplace in recent years as a preamble to and justification for large cooperative national and international field programmes. I suspect that is its origin.

Carl Wunsch is Professor of Physical Oceanography and acting Head of the Department of Earth and Planetary Sciences, Massachusetts Institute of Technology.

Outstanding Titles in Optics

Contemporary Optics

by **A. K. Ghatak** and **K. Thyagarajan**
Indian Institute of Technology at New Delhi

Provides a detailed problematic approach to the study of underlying mathematical and physical principles of modern laser applications. A volume in *Optical Physics and Engineering*. approx. 365 pp., illus., 1978, \$39.00/£20.48

Computer Modeling of Gas Lasers

by **Kenneth Smith** and **R. M. Thomson**
University of Leeds, England

Uses the carbon dioxide laser as an example in detailing gas kinetics, excitation processes, hydrodynamics, injection locking, and other important aspects of gas lasers. A volume in *Optical Physics and Engineering*. 430 pp., illus., 1978, \$51.00/£26.78

Laser and Coherence Spectroscopy

edited by **Jeffrey I. Steinfeld**
Massachusetts Institute of Technology

Active researchers in the field of chemical physics examine coherent absorption and scattering phenomena in the spectroscopy of atoms and molecules. approx. 515 pp., illus., 1978, \$54.00/£28.35

High-Power Lasers and Laser Plasmas

edited by **N. G. Basov**
Academy of Sciences of the USSR, Moscow
Translated from Russian by **J. George Adashiko**

Examines Mandel'shtam-Brillouin scattering lasers, high-power compressed-gas lasers, the absorption and reflection of intense laser radiation in a laser plasma, and the cumulative phenomena. *The Lebedev Physics Institute Series, Volume 85*. approx. 225 pp., illus., 1978, \$47.40/£24.89

Coherent Cooperative Phenomena

edited by **N. G. Basov**
Academy of Sciences of the USSR, Moscow
Translated from Russian by **Donald H. McNeill**

This volume examines the experimental and theoretical aspects of cooperative optical effects in multilevel molecular and atomic systems. *The Lebedev Physics Institute Series, Volume 87*. approx. 150 pp., illus., 1978, \$35.40/£18.59

Physics of Thin Films

by **Ludmila Eckertová**
Charles University, Prague, Czechoslovakia

Examines the preparation, measurement, and characteristics of thin films and their applications in optics and microelectronics. 245 pp., 1978, \$33.00/£17.33

Transform Techniques in Chemistry

edited by **Peter R. Griffiths**
Ohio University

This comprehensive introduction to transform techniques in chemistry, interdisciplinary in design, examines Fourier transform spectroscopy and the use of computers with chemical instrumentation. A volume in *Modern Analytical Chemistry*. approx. 390 pp., illus., 1978, \$47.40/£24.89

Laser Systems in Flow Measurement

by **Tariq S. Durrani**
University of Strathclyde, Scotland
and **Clive A. Greated**
University of Edinburgh, Scotland

Describes basic optical components and signal analysis hardware, and also provides introductory material on turbulence statistics. A volume in *Optical Physics and Engineering*. 304 pp., illus., 1976, \$33.00/£17.33

Handbook of the Birds of Europe, the Middle East, and North Africa

The Birds of the Western Palearctic

Volume 1 Ostrich to Ducks

Edited by Stanley Cramp and K.E.L. Simmons

Great advances have been made in ornithology in recent years. This new *Handbook* is planned as a comprehensive and authoritative reference work for both the professional scientist and the amateur ornithologist. The seven volumes will cover all the 795 species of birds occurring in the area.

Volume I, just published, covers the Ostrich; Divers; Grebes; Albatrosses; Petrels and Shearwaters; Storm-petrels; Tropicbirds; Gannets and Boobies; Cormorants; Pelicans; Frigate birds; Bitterns, Egrets, Darters, and Herons; Storks; Ibises and Spoonbills; Flamingoes; Swans, Geese, and Ducks.

Don't settle for half the literature loaf.

Now you can get the "whole" loaf with **BioResearch Index (Biol)**. Certainly **BIOSIS** selects, abstracts and indexes more than 149,000 primary journal articles in **Biological Abstracts** every year . . . but there's more to life science literature than that. Much more.

In **Biol** we meticulously search and report on—

- Research Communications •
- Notes • Reports • Symposia •
- Proceedings • Meeting Abstracts • Monographs

These add up to 113,000 *additional* items which appear each year in **Biol** from thousands of sources.

You can leisurely browse the contents pages or quickly find special interests indexed by—

- Subject • Author • Field of Interest • Organism (Biosystematic/Generic).

See what's in the oven throughout the entire world. Write or call today for full subscription information:

Physical aspects of biological systems

Biophysik: Ein Lehrbuch. Edited by W. Hoppe, W. Lohmann, H. Markl and H. Ziegler. Pp. 720. (Springer: Berlin, Heidelberg and New York, 1977.) DM98; \$43.20.

A TEXTBOOK which describes biophysical approaches and physical aspects of biological systems would fill a gap, because most existing books deal with methods preferentially. The present book written by 54 authors, mostly from Germany, takes an interesting step in this direction.

The strongest part of the book is contained in the many chapters on biophysical aspects of various systems written by many well known workers in the field. These contributions range from enzymes as catalysts (Huber), membranes (Fisher, Stoeckenius, Sackmann and Frömter) and receptors (Thurm, Kaissling, Menzel, Snyder and Stieve), through photosynthesis (Renger) and muscle-contraction (Mannherz, Holmes) to complex systems such as information transduction in nerve systems (Creutzfeldt), orientation in flight (Reichardt), biomechanics of flight (Nachtigall) and transport of water in plants (Ziegler)—to mention only a few examples. Most of these contributions are very informative reviews of 10–20 pages written for undergraduate students or scientists who wish to broaden the scope of their knowledge. They provide a convenient source of information for many facets of biophysics and cannot be found in such a concise way in other textbooks. Three purely biological or biochemical chapters on the living cell (Schnepf), chemical structure of biological macromolecules (Tschesche) and biological function of nucleic acids (Zillig) are useful, but the information can be found also in other texts.

Chapters dealing with more general aspects of biophysics such as intra- and intermolecular interactions (Hofacker and Ladik), energy transfer (Dörr and Kuhn), cybernetics (Marko) or evolution (Kuhn and Schuster) do not add up to a complete picture. This part of the book naturally suffers more than the other part from the way it was written, namely by many rather specialised authors. For example, the chapter on interactions, written by two theoretical chemists, emphasises the quantum mechanical approach for the theoretical calculation of hydrogen bonds and charge transfer complexes but leaves out hydrophobic interactions and other important contributions.

Chapters on energetics and kinetics contain a basic sketch of general thermodynamics and fundamental kinetics without much emphasis on biological problems. Sections on thermodynamics of macromolecules in solution, multiple equilibria, polyelectrolytes, and so on, would have been valuable. Surprisingly the dynamic aspect of the function of biological macromolecules are not treated, although a good section on fast kinetic methods (Rüppel) is included.

A chapter on physical methods for the investigation of biological macromolecules is of heterogeneous quality. The description of methods for solutions cannot compete with good intro-

ductionary texts such as Van Holde's *Biophysical Chemistry*.

Lecturers and students who are engaged in courses of biophysics would welcome a text on general biophysics. The present book cannot be recommended as a basic text but it may serve as a supplementary book for advanced reading. A difficulty for a worldwide use of the book arises from the fact that it is written in German. This is an anachronism for a book of this type, but perhaps an English translation is planned.

Jürgen Engel

Jürgen Engel is Professor of Biophysical Chemistry at the Biozentrum of the University of Basel, Switzerland.

Indignation against mercury pollution

Mercury Contamination: A Human Tragedy. By P. A. D'Itri and F. M. D'Itri. Pp. xxii+311. (Wiley: New York, London, Sydney and Toronto, 1977.) £13.45; \$22.80.

THE aim of this book is to raise indignation against environmental pollution in general, and pollution by mercury in particular. Beyond the problem of environmental pollution, there is an historical account on the use of mercury. The story of its medicinal use, especially for the treatment of syphilis (as presented by the authors), is a warning to scientists to analyse all information critically and not to substitute possibilities for facts. Unfortunately, the authors do not draw the same conclusion.

There is no doubt about the environmental impact of mercury pollution in the North American lakes and rivers; there is no doubt about the unacceptably high level of methylmercury in fish caught in some of these waters; there is no doubt that methylmercury is a highly toxic accumulative poison, but these facts are not substitutes for the complete lack of controlled morbidity data for the populations of White Dog and Grassy Narrows Reserves. The lack of morbidity or mortality data, to say the least, is surprising. It is alleged that an official admitted "it was a wonder more Ojibways (of the Grassy Narrows) were not dying because some of them had blood mercury levels that exceeded those of fishermen who died at Minamata". It is also surprising that these Indians had higher blood levels than fishermen at Minamata, as, according to the authors, the highest hair level of the members of the Ojibway tribe was 40% lower than the hair level at which Japanese at Minamata began to show

symptoms. Another reason for surprise is that blood mercury concentrations were not estimated in the victims of the Minamata epidemic. In the same chapter there is another misquotation or uncritical quotation which states that 200 g fish consumed for 3 weeks raises the mercury concentration in the blood to 2 p.p.m. A 70-kg man, however, ought to consume 10.7 mg mercury as methylmercury per day for 3 weeks to produce 2 p.p.m. blood concentration—that is, he should eat fish containing an unbelievably high (more than 50 p.p.m.) concentration of mercury.

These and similar overstatements do not help but rather weaken the impact of the book. Mercury, according to the authors, injures at a lower dose and at an earlier time than scientific evidence indicates. As they suspect that mercury had some role in the death of Napoleon, they bring forward his death before the One Hundred Days and Waterloo to the time of his first exile on the Isle of Elba.

These criticism might seem unjustified, as in the preface the authors made it clear that "The book was not written for scientists who conduct research into mercury pollution", probably because compared with the *Toronto Globe and Mail*, and the *Kenora Daily Miner and News*, the scientists are inferior as creators and absorbers of information. First of all, "The scientific method by definition is partial and incomplete" (which is true); secondly, "local citizens instinctively grasp the problem and insist on resolution while scientists are still trying to ensure that their findings are accurate"; and thirdly, even if they are able to grasp the problem "the scientists carefully qualified statements may confuse the public."

Laszlo Magos is a Senior Scientific Officer at the MRC Toxicology Unit, Carshalton, Surrey, UK.

Quantum pharmacology

Quantum Pharmacology. By W. G. Richards. Pp. xiii+213. (Butterworth: Sevenoaks, UK, 1977.) £12.

THE relationship between the chemical structure of small molecules and their biological effects has been studied intensively for over a hundred years. Apart from its intrinsic interest, it is obviously of enormous practical importance in the design of drugs. In recent years, studies of this relationship have been growing steadily in sophistication. The biological effects can now be described in greater detail, often in terms of binding to isolatable receptors and enzymes rather than gross physiological effects. The structural properties of the small molecules, too, are now discussed with greater precision, considering their three-dimensional conformation and electron distribution rather than simply two-dimensional representations of their covalent structure. In the latter area, the past ten years have seen increasing application of molecular orbital methods to molecules of pharmacological interest, and Dr Richards, one of the leading practitioners of this interdisciplinary art, has now written an introduction to the field.

The stated aim of the book is twofold, to introduce medicinal chemists to molecular orbital calculations and to introduce theoreticians to the pharmacological problems to which their methods can be applied. Thus, the book begins with an outline (in 87 pages) of some basic pharmacology, lucidly presented though necessarily very condensed. The emphasis is primarily on the cholinergic and adrenergic systems, histamine and centrally acting drugs, with chemotherapy, prostaglandins and peptide hormones, for example, receiving only brief mention.

The second part (49 pages) introduces molecular orbital calculations. The fundamental properties of wave functions and molecular orbitals are described very clearly, as is their use to calculate molecular properties. There is a valuable chapter in which the various approximate wave functions are described and compared.

In many ways the core of the book is the third section (38 pages), as it is here that the applications of theory to experiment are discussed. The first topic is that of the conformation of the small molecule, illustrated by calculations on a number of neurotransmitters and, in particular, on a series of histamine derivatives. The latter illustrate the "essential conformation approach" developed by the author, in which the biological activity of a series of compounds is correlated with the region of conformational space which they can occupy, and a region of this space which

is in some sense essential for activity is thus defined. Since most conformational calculations consider the small molecule in isolation (*in vacuo*), the next chapter is devoted to a discussion of approaches to the problem of including the effects of solvent (specifically water) in the calculations. The remaining chapters focus on electron distribution—both on empirical correlations with activity, and on the use of the electrostatic potential field of the small molecule as a method of "mapping" the complementary surface of the receptor site (introduced by Weinstein and his colleagues). It is a pity that this section of the book is so brief. It would have been valuable to have a more extensive discussion of some of the many interesting points raised, perhaps at the expense of a shorter pharmacological introduction, for which many introductory texts are available. The book concludes with a very valuable annotated bibliography of all molecular orbital studies of molecules of pharmacological interest reported up to the end of 1976.

Can calculations be useful? The author concludes with a cautious "yes", with which I am sure most readers will agree. The ways in which they are best used remains, to some extent, to be established. There is no question that molecular orbital calculations have revealed interesting correlations between molecular properties and biological activity—as, for example, in the "essential conformation approach" to histamine analogues—and these will continue to be a valuable aid to the rational design of new compounds. What we do not know is how such correlations can be interpreted in physical terms to help build up a picture of the receptor site. There is no doubt that further work in this field will be stimulated and guided by Dr Richards' lucid and critical description of the state of the art.

Gordon C. K. Roberts

Gordon C. K. Roberts is a member of the scientific staff of the Medical Research Council in the Division of Molecular Pharmacology, National Institute for Medical Research, London, UK.

Remote sensing techniques

Aerial Photography and Remote Sensing for Soil Survey. By L. P. White. Pp. viii+104 (Clarendon/Oxford University: Oxford, 1977.) £6.

THE foreword to this book indicates that it is the first of a series of new handbooks following in the footsteps of Robin Clarke's classic *The Study of the Soil in the Field*. This is a disappointing book, mainly because it does not fulfil the expectations aroused by the title and preface. In short, the balance of the book seems to be out of keeping with the topic. Only one chapter (some eleven pages) is directly concerned with soil survey and aerial photography. The remainder of the main text of 93 pages consists of a concise discussion of remote sensing methods, sensors and platforms, which other texts have dealt with in a more comprehensive manner.

Readers concerned with the use of remote sensing techniques in soil survey will turn their attention to chapter 4. Those familiar with image interpretation will doubtless recognise the wide range of issues touched on here. The brevity of the treatment, however, results in a failure to discuss in any depth the many aspects of the relationships between soil mapping units and image characteristics. For example, the treatment of terrain analysis is rather perfunctory, and the topics of pedo-

logical analysis and photo-interpretation keys merit further discussion. A much fuller treatment of the value of images/photographs for the detection of temporal variations in soil conditions (for example, structure and profile drainage) would have been useful. Similarly, more attention could have been given to definitions of soil mapping units, their relationships to different scales of imagery, and the testing of the accuracy of interpretation.

The bulk of the book comprises descriptions of photography and photographic products, line-scanners, side looking radar, imagery from space platforms, image enhancement, and automatic analysis. There is, however, little significant comment on the sensors, platforms and techniques in relation to soil survey. Indeed, the illustrative plates have captions dealing with vegetation, relief and land use, rather than soil conditions or soil boundaries. Some plates are in colour.

A wider selection of references would have been appropriate in a volume of this kind. For example, the work of Beckett, Evans, Mitchell and Western would suggest some of the pathways towards greater use of remote sensing.

The line diagrams are good but there are some typographical errors such as incorrect naming of the general editors on the dust jacket.

Presenting the best in
laser equipment

HELIUM-NEON LASERS

from Hughes Aircraft Company

Hughes advanced technology and volume production methods have produced helium-neon laser systems which are attractive to a wide spectrum of users.

At one extreme, versatile and reliable sub-systems will satisfy the OEM market with large quantities of a proven product for use in such areas as information handling, construction, medical instrumentation and industrial process control.

At the other, the small quantity customer gains equally from the experience and capability of Hughes and is able to select laser tubes, heads or systems from a wide range of output powers.

This is one product group from the Company which offers a wide choice of optics, electronics, electro-optics and laser equipment from leading high technology manufacturers.

Please send me full details of
the Hughes range of Helium-Neon Lasers.

what's new—lasers, optics, holography

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. More detailed information may be obtained by circling the appropriate numbers on the Reader Enquiry Card, bound inside the cover. A feature on centrifuges and rotary evaporators will appear in the 16 February issue.

Coherent. The Coherent Supergraphite series of argon and krypton ion lasers comprises 13 different models with 40 different configurations, providing multiline output power of from 800 mW to over 18 W TEM₀₀. With the ultraviolet option these systems will deliver up to 3.0 W guaranteed in the ultraviolet. Coherent krypton lasers have guaranteed TEM₀₀ output as high as 4.6 W in red wavelengths 3.0 W in the violet and 2.0 W in the ultraviolet. The Coherent CR series of dye lasers features a crystalline quartz birefringent filter which combines extremely low optical loss with precise tuning. Linewidth is resettable and the whole system is designed for ease of use. Optical components are mounted in a 2-inch diameter Invar rod for maximum amplitude and frequency stability. The CR 599 scanning dye laser system incorporates active closed-loop stabilisation to provide narrow linewidth and stable operation. The Coherent picosecond pulse package is based on Coherent ion and dye lasers and offers controlled pulse width and peak power, while the picosecond pulse picker ensures repetition rates. The new Model 307 'Noise Eater' can stand alone in front of any laser and give a

Laser equipment from Coherent

reduction of 40 db/d.c. and 26 db/1 MHz. Other Coherent equipment available includes collimators and lenses, mode lockers, interferometers, modulators, power meters and optics.

Circle No. 25 on Reader Enquiry Card

Korad. Korad manufacture holographic laser systems for both reflection and transmission holography. Features include long coherence lengths, excellent wavelength repeatability, and availability as single and double pulse systems. The Korad mobile holocamera is completely self-contained and weighs less than 200 lb. The holocamera can accommodate any of the more than 20 different laser systems now available. The Pockels cell Q-switch KQS2 and KQS2DP laser

Korad KHCI holocamera

systems provide a precisely controlled laser pulse and are particularly suited to applications involving plasma and shock phenomena. Korad offer an extensive range of holographic accessories; these include alignment and reconstruction systems, the KA autocollimator, the KD1 photodetector, KDG delay generator and the 99/102C energy measurement system.

Circle No. 26 on Reader Enquiry Card

Hartley Measurements. The model 215G grating-tuned TEA CO₂ laser is a compact high energy density system: the 2-J multimode output has a gain switched spike only 40 ns wide, providing a peak power in excess of 15 MW. For TEM operation 0.7 J can be obtained in a 6-mm diameter beam of 3 milliradians divergence. Repetition rate is continuously adjustable from 0.2 to 2 ps. Manual push button/single shot firing are also available as standard. Full optics are provided with the unit and tuning is by means of a grating of 150 lines per mm. The unit is completely self-contained with a built-in power supply and all controls mounted in the laser housing.

Circle No. 27 on Reader Enquiry Card

J K Lasers produce the System 2000 range of pulsed solid-state laser equipment. An updated set of data is available to explain the system, and

applications covered include holography, phytochemistry, plasma diagnostics, welding and drilling. The J K Lasers range of pulsed ruby lasers designed for use in holography has been extended to include a 10-J single-mode system. This high output energy has been achieved by two-stage amplification of a well-proven holographic oscillator. The system is capable of taking holograms of objects within a 5-m cube. As 1 J of the output energy can be used as the reference beam, large-format holograms of up to 1 m² can be made from a single pulse. J K Lasers will shortly be offering a range of standard dye lasers suitable for pumping with their solid state lasers. These models will be available with a full range of dyes, operating throughout the spectral range 400–800 nm.

Circle No. 28 on Reader Enquiry Card

J K Lasers 2000 pulsed ruby laser

Electro-Photonics. The Electro-Photonics range includes a comprehensive range of flashlamp pumped dye laser systems, wavelength tunable across the entire visible spectrum, with options of mode-locking to produce picosecond laser pulses and second harmonic generation to provide tunable laser radiation in the ultraviolet. One interesting application is a new technique of 'rapid optical sampling of relaxation phenomena, involving two time-correlated picosecond pulse trains'. Two flashlamp-pumped, mode-locked and optically coupled dye lasers produce trains of picosecond pulses with definite, but variable time correlation. One pulse train is used to bleach the sample, while the other probes the decay of its transient transmission. Relaxation times between 15 ps and 1 ns can be monitored by one simultaneous activation of the two lasers that is, a single shot technique. In previous experiments each point of the relaxation decay curve was measured by splitting one laser pulse train and mechanically varying the delay between

excitation and probe pulses between laser firings. There was also an added restriction that transmission measurements were limited to the probe wavelength. In this new technique, the probe wavelength can be tuned over a considerable wavelength range. Electro-Photonics also have developed systems for remote sensing of atmospheric pollution, in particular SO_2 and NO_2 . The technique used is differential absorption. The Electro-Photonics range includes the Model 23 high repetition rate dye laser, the Model 33 mode-locked dye laser and the Model 43 high-energy dye laser.

Circle No. 29 on Reader Enquiry Card

Malvern Instruments. The Malvern ST 1800 particle and droplet size distribution analyser functions over the range 1–500 μm . The analyser depends on the principle of laser-illuminated Fraunhofer diffraction scattering: the diffraction pattern generated by each particle is independent of its position in the beam, so measurements can be made with a particle moving at any speed. For a group of particles or droplets the combined diffraction pattern is uniquely related to the size distribution. The output from the detector system is processed to provide hard-copy paper print readout of percentage and cumulative weight distribution, and of the degree of obscuration. Particles in the size range 25 \AA –1 μm can be sized by use of the System 4300 photon correlation spectrometer. Particles moving in a laser beam under Brownian motion yield, when examined by photon correlation, their diffusion coefficients and hence by Stokes-Einstein's equation, the hydrodynamic radius. Polymers, surfactants, colloids, micelles, emulsions, proteins and RNA molecules can all be studied in this way. The Malvern Type 6200 laser photon correlation anemometer measures flow velocities and turbulence.

Malvern 4300 (top) and 6200⁺ systems

Electro Optic Developments. Products from Electro Optics include sub-nano-second rise time Pockels cells, wideband low voltage video modulators, phase modulators for laser anemometry, optical harmonic generators, high voltage amplifiers and pulse generators. The standard optical components offered include calcite polarisers and quartz retardation plates. Five years of active development work on wideband interference-free optical data telemetry links have culminated in the FOL 100 fibre optic link. This 150 MHz base bandwidth system features a compact,

Electro Optics FOL 100

rugged transmitter powered by rechargeable NiCd batteries. The transmitter sensitivity can be remotely selected at the receiver by means of a control fibre running parallel to the signal fibre. Transmission distance is 50m for 43dB SNR or 200m for 40dB SNR.

Circle No. 31 on Reader Enquiry Card

Combined Optical Industries. Combined Optical Industries of Slough offer a wide range of top quality magnifiers manufactured from optical grade plastics material.

Circle No. 32 on Reader Enquiry Card

Laser Lines. High peak powers at repetition rates of up to 100 Hz can be generated when a nitrogen laser is used as a pump. The self-contained Laser Lines Molelectron nitrogen laser can be used in this way as a pump for the new Molelectron DLII series of dye lasers to give complete coverage from 360 to 930 nm. These dye lasers all incorporate a new four-beam expander which is completely achromatic and expands the beam only at right angles to the rulings of the grating. This enables the standard laser to have a linewidth of 0.01 nm at 460 nm which can be reduced to 0.0006 nm when an air-spaced etalon is placed in the laser cavity. The DLII laser systems have an oscillator amplifier configuration. Only 25% of the pump beam is used in the laser oscillator, thus avoiding saturation effects, and the remainder is used in the amplifier. These systems can be used in conventional absorption and fluorescent emission spectroscopy, and the high powers and narrow linewidth enable more difficult techniques such as Raman and coherent anti-stokes Raman scattering (CARS) to be used.

Circle No. 33 on Reader Enquiry Card

Hakuto International. Recent additions to the HTV range of photomultiplier tubes are designed specifically for use in conjunction with helium neon lasers operating in the range 185–850 nm. Various types of head-on and side-on photomultipliers are available, ranging in size from $\frac{1}{4}$ to 5 inches in diameter, with spectral response up to 930 nm.

Circle No. 34 on Reader Enquiry Card

OCLI Optical Coatings. OCLI specialise in optical thin film coatings in laser systems. Increased use of lasers has introduced the additional hazard of eye damage by laser beams entering visual viewing sighting systems. OCLI Europe have developed a durable coating that can be applied to any surface in the optical system without requiring optical redesign, to provide protection against ultraviolet ruby and yag lasers simultaneously, whilst maintaining good visual transmission. OCLI also supply coated optics specifically designed for use in laser fusion and other advanced systems resulting in power densities greater than conventional coatings can withstand. These include windows, mirrors and polarisers.

Circle No. 35 on Reader Enquiry Card

Carl Zeiss Inc. The new Zeiss flatfield, long-working distance Epiplan microscope objectives are for brightfield and darkfield work. They are highly effective for manipulation under the microscope, offering extra protection against damage because of the long working distance (minimum 2 mm).

Circle No. 36 on Reader Enquiry Card

Zeiss Epiplan objectives

Macam Photometrics. The Macam Modern Optics Educational System has been specially designed to teach a wide range of physical optics techniques, including laser optics, diffraction, interferometry and the very versatile technique of holography. Macam also produce a range of photometers for the accurate measurement of the luminous flux of a wide range of lamps.

Tune into Coherent picosecond pulsing

**for controlled pulse width and peak power
(with the birefringent filter) and
repetition rates (with the
picosecond pulse picker)**

Europe's leading scientists are using the Coherent 590 dye laser system for research with picosecond pulses.

The Coherent system is the only one to have a birefringent filter to control pulse duration from one to 10 picoseconds. It is also the only system with an electro-optic picosecond pulse picker which allows reduction of repetition rates from 100 MHz down to any convenient value. It is this innovation in design that leads to the outstanding performance of all Coherent products.

Coherent have a complete range of lasers and electro-optic components to meet the demanding needs of today's research. For further information write or phone Coherent now.

Coherent 590-03 dye laser synchronously pumped by a mode locked CR12 argon laser.

**Great Chromatograms
come from
Great Beginnings.**

**And in the beginning,
Rheodyne valves,
HPLC columns
and filters should
be there.**

We're the front-end company in high pressure liquid chromatography. Almost everything you need to make better chromatograms in the beginning is on our shelf.

The 70-10 Sample Injection Valve. Here's a 6-port sample injection valve with a removable sample loop and 7000 psi pressure rating. Size, 10 μ l to 2.0 ml.

The 7120 Syringe Loading Sample Injector. Fill loops conventionally or in the partial loop variable volume mode with only 0.5 μ l sample loss.

Teflon Rotary Valves. For about half the cost you'd expect to pay, we offer three, four and six way valves in 0.8 mm and 1.5 mm bores. Features zero dead volume, chemical inertness and 300 psi rating.

HPLC Columns. Here are the columns with guaranteed peak symmetry and minimum plates per meter to doubly assure optimum column performance. Twelve columns currently available. Types include adsorption, reverse phase, polar bonded phases and ion exchangers.

The Column Inlet Filter. It costs very little, but it can save you a boatload of trouble. Place this low dead volume filter between the injection valve and column to protect column inlet frits from plugging.

The Model 7037 Pressure Relief Valve. Protect your set-up against damage from over pressure (2000 to 7000 psi setting range).

Write or call for more information. Address Rheodyne Inc., 2809 Tenth Street, Berkeley, California 94710. Phone (415) 548-5374.

Rheodyne distributors are located throughout the world.

Seed Pathology Volumes 1 and 2

Paul Neergaard

This is a unique and comprehensive compilation of the most recent data on the subject, brought together by an internationally recognised authority. It is the first book in this field and it is thoroughly up to date.

Paul Neergaard gives a comprehensive survey of research and current concepts relating to seed-borne diseases, the methods used for their identification and control, the mechanics of their transmission through seeds, procedures for laboratory seed testing, and the risk assessment of crop losses due to seed-borne diseases. The book will have a wide application both as a university textbook and as a practical guide and reference work for those involved in almost any sphere of the subject.

Contents

Volume 1 – Part 1: Pathogens – Diseases – Hosts –
Economic Significance of Seed-Borne Diseases –
Diseases and Injuries of Seed – Seed-Borne Viruses –
Seed-Borne Bacteria – Seed-Borne Fungi – Seed-Borne
Nematodes – Storage Fungi – Impact of Seed-Borne and
Storage Fungi on Animal and Human Health – Types of
Host in Relation to Types of Pathogen – Morphology and
Anatomy of Seeds in Relation to Transmission of
Pathogens.

Part II: Mechanisms of Seed Transmission –
Introduction to Part II – Environment and Plant-Seed
Infection – Entry Points of Seed Infection – Infected or
Contaminated Parts of the Seed – Seed-Plant
Transmission, Establishment of Infection and Course of
Disease – Environmental Physicochemical Factors
Affecting Establishment and Course of Disease –
Environmental Biotic Factors Affecting Establishment
and Course of Disease – Intermittent – Factors Inherent
in the Pathogen Affecting Establishment and Course of
Disease.

Volume 2 – Part III: Principles of Control –
Introduction to Part III – Seed Crop Management –
Management of Seed Storage – Seed Treatment,
Procedures and Equipment – Mechanism and Practical
Use of Chemical Seed Treatment – Testing Seed
Germicides and Treated Seed – Quarantine for Seed.

Part IV: Seed Health Testing Methods –
Objectives of Seed Health Tests – Sampling –
Examination of Ungerminated Seed – Incubation Tests
1: Procedures – Incubation Tests II: Factors Affecting
Test Results – Bioassays and Biochemical Procedures –
Inspection of Plants Beyond the Seedling Stage.

Part V: Assessment of Seed-Borne Inoculum –
Forecasting Losses from Seed-Borne Diseases and
Assessing Disease Tolerances for Seed Testing.

RESOURCE Scientist, Ph.D., 37, seeking 1 to 3 yr., mgt./teaching/research position overseas. Background of contract research and science advisory in topics of water quality, marine resources and coastal land use planning and in areas of policy analysis, impact assessment and resource mgt. Nine years varied experience in field, lab. and office modes. Résumé, reports and papers available. Reply to: D. Zoelner, 5322 41st St., N.W., Washington, D.C. 20015. 1103(B)

AMERICAN Zoologist/Ethologist. Ph.D. (1974). 14 publications. French and German National Postdoctoral Fellowships. Five years university teaching. Four years admin. and consultant exp. (U.S. Naval Officer, G.E. Co.). Conversant Eng., Fr., Ger., It., Grk. Seeks teaching, research, or interesting alternative position after June 1978. Box No. 1047(B).

INORGANIC Chemist, aged 35, 36 publications, recently redundant in closing teachers training College seeks position U.K. or overseas. Box No. 1046(B).

APPOINTMENTS VACANT

UNIVERSITY OF SYDNEY LECTURESHIP IN ORGANIC CHEMISTRY

Applicants must have research interests in a mainstream area of Organic Chemistry.

The position is permanent but may be filled for three years in the first instance with possibility of permanency during that time, or in certain cases return fares. Appointee should preferably be able to commence duties in July 1978.

Salary range: SA14,851 to SA19,551 p.a.

Applications including curriculum vitae, list of publications and names of three referees by March 20, 1978, to the Registrar, University of Sydney, NSW 2006, Australia. Enquiries to Professor S. Sternhell, School of Chemistry, in the University. Conditions of appointment available from Association of Commonwealth Universities (Apsus), 36 Gordon Square, London WC1H 0PF. 1119(A)

FACULTY OPENING IN BIOCHEMISTRY University of Illinois Champaign-Urbana

The Department of Biochemistry is seeking applicants for a tenure track appointment at the level of Assistant Professor or higher to begin August, 1978. Applicants should be qualified to teach biochemistry courses at undergraduate and graduate levels. Only candidates who have demonstrated excellence in research and who are prepared to establish an active research program will be considered, preference will be given to those who have received graduate and postdoctoral training in strong research environments. The minimum salary at the Assistant Professor level is \$15,000 for a nine-month appointment; salaries at higher ranks are negotiable. For full consideration, application materials, including a curriculum vitae, a list of publications, a brief description of research interests and three letters of reference should be sent by February 1, 1978 to:

Professor Lowell P. Hager, Head
Department of Biochemistry
University of Illinois
Urbana, Illinois 61801
Telephone: (277) 333-3945.
The University of Illinois is an
Affirmative Action/Equal Opportunity Employer. 836(A)

UNIVERSITY OF BATH SCHOOL OF PHARMACY AND PHARMACOLOGY

Applications are invited for the following posts:

LECTURER IN PHARMACEUTICS (Ref. 77/158)

This appointment offers opportunity for a suitably qualified and experienced pharmacist to participate in the teaching and established research programme in the field of Pharmaceutics.

LECTURER IN PHYTOCHEMISTRY (Ref. 77/159) N

Applicants should be appropriately qualified and have experience in the chemistry of biologically active natural products.

Salary scale (under review) is £3,333 to £6,655; the starting salary will be set in the lower part of the scale.

Application forms and further particulars are obtainable from the Personnel Officer, University of Bath, Bath BA2 7AY. Please quote appropriate reference number. Closing date for applications: February 16, 1978. 1074(A)

UNIVERSITY OF JORDAN

Faculty positions: in Electrical Machines, Electronics and Electromagnetics available 1978. Doctorate and strong credentials are required. Responsibilities will include teaching, setting-up Laboratories and research. Rank and salary will be based on qualifications. Please send résumé with full information to the Dean, Faculty of Engineering and Technology, Jordan University, Amman, Jordan. 1044(A)

University of Bristol

LONG ASHTON RESEARCH STATION

Head of Crop Protection Division

The research staff is to be reorganised into four Divisions; the one concerned with chemical and biological crop protection will include fifty-five Science Group staff in varied disciplines. The work will concentrate, initially, on the principles of fungicidal activity, but will also comprise the strategy of crop protection, its ecological consequences and the practicability of biological control. Host and pest/pathogen combinations to be studied will include those suited to other work in the Station, and to plant pests and diseases important in the agriculture of South West Britain; collaborative work with other agricultural research institutions will be an important feature.

Appointment will be in the Senior Principal Scientific Officer grade (£8,858 to £10,006 per annum, including current pay supplements). Non-contributory superannuation scheme.

Applicants must have a good honours degree or equivalent in a relevant discipline, and considerable experience in the chemistry or biology of crop protection. As the post requires inspiring direction of staff expert in varied disciplines, and ability in scientific administration, great importance will be attached to personality, experience and the ability to foster collaborative work within and beyond the Division.

Further particulars from the Secretary, Long Ashton Research Station, Long Ashton, Bristol BS18 9AF, to whom applications together with the names of three referees should be sent not later than February 10, 1978. 1035(A)

UNIVERSITY OF LONDON

READERSHIP IN STATISTICS at

Imperial College of Science and Technology

The Senate invites applications for the above Readership tenable in the Department of Mathematics at the College.

The Reader will be required to have substantial research experience in theoretical or applied statistics or in applied probability theory or in the mathematical and probabilistic aspects of operational research. Supervision of postgraduate students will be an important part of the duties, as will lecturing on statistics to students of mathematics and engineering. The salary scale is £6,443 to £7,951 plus £450 London Allowance.

Applications (10 copies) must be received not later than February 15, 1978 by the Academic Registrar, (N) University of London, Senate House, London WC1E 7HU, from whom further particulars should first be obtained. 1102(A)

THE DISTILLERS COMPANY LIMITED FERMENTATION BIOCHEMIST

The Yeast and Food Division of the Distillers Company Limited requires a graduate to work in their small scale Pilot Plant at Glenochil Technical Centre, Menstrie, Clackmannanshire. Studies carried out in this Pilot Plant include yeast strain selection work, process development and examination of raw materials.

Applicants, who should preferably be under 28 years old, must have a degree in microbiology, biochemistry or closely related subjects together with relevant postgraduate experience. One or two years commercial or research experience with yeast would be an advantage.

Further details together with an application form can be obtained by writing to:

The Yeast Research Manager,
Yeast and Food Division,
The Distillers Company Limited,
Glenochil Technical Centre,
MENSTRIE,
Clackmannanshire FK11 7ES.
1016(A)

Experimental Officers

-Physical Chemistry

We have vacancies for two Experimental Officers in the Physical Methods Section of Research Department. The first is in a group undertaking kinetic and mechanistic studies for process development and stability evaluation of candidate drugs. The second is in a group investigating compounds' physico-chemical properties in relation to drug designs.

The candidates for both vacancies should be recently qualified (under 26), possess a degree or equivalent, have a special interest in physical organic chemistry and be familiar with analytical methods e.g. UV spectroscopy, potentiometry, HPLC etc. They should be able to combine precise experimental technique with judgement of data whilst remaining under the overall guidance of a Senior Chemist.

Previous experience in reaction kinetics

or knowledge of enzyme structure and mechanism would be helpful for the respective vacancies but is not essential.

Our modern research laboratories are situated in pleasant surroundings but within easy reach of main road and rail routes. Conditions of service, salary and assistance to married staff in moving house are designed to attract and retain staff of high calibre.

Please write giving details of qualifications and experience to:

Mr. M.J. Higgins, Personnel Officer
Imperial Chemical Industries Limited

Pharmaceuticals
Division
Meresside Research
Laboratories
Alderley Park
Nr. Macclesfield
Cheshire

1059(A)

THE ROYAL VETERINARY COLLEGE

University of London

Division of Preclinical Studies

DEPARTMENT OF ANATOMY

Applications are invited for the post of
LECTURER IN ANATOMY

The post becomes vacant on September 1, 1978, and is based at Camden Town. The person appointed will be expected to undertake teaching of the anatomy of large animals and will be expected to engage in research.

SALARY SCALE (under review): £3,805 to £7,105 including London Allowance. Initial salary determined by qualifications and experience. Superannuation under the Universities' scheme. Removal expenses up to £650 may be reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone: 01-387 2898.

CLOSING DATE FOR APPLICATIONS: February 24, 1978. 1125(A)

UNIVERSITY OF QUEENSLAND

Australia

**LECTURER IN
CROP SCIENCE**

DEPARTMENT OF
AGRICULTURE

To lecture in various aspects of crop (field, plantation or horticultural) production. Higher degree in Agricultural Science, or Science with agricultural experience. Demonstrated research capability in some aspect such as Crop Ecology, Crop Physiology or Cropping systems. March 6, 1978.

Salary: \$A14,632 to \$A19,262 per annum. Other Benefits: Superannuation, housing assistance, study leave, travelling and removal expenses.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 1085(A)

THE SCHOOL OF PHARMACY UNIVERSITY OF LONDON LECTURESHIP AND TEACHING FELLOWSHIP IN PHARMACOLOGY

Applications are invited for both these appointments effective at or about September 1, 1978 from suitably qualified persons.

For the Lectureship, postdoctoral teaching and research experience is required and an interest in Psychopharmacology, Cardiovascular Pharmacology or Endocrinology would be welcome.

For the Teaching Fellowship, which is of limited term, postgraduate research experience is required except for medical graduates.

Normal non-clinical university academic terms of appointment and salary scale. Further information can be obtained from Professor D. W. Straughan.

Applications to be submitted by February 6, 1978 in the form of letter accompanied by a C.V. and the names of two referees, to: The Personnel Officer, (N) The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX. 1034(A)

NATIONAL INSTITUTE OF AGRICULTURAL BOTANY REGIONAL TRIALS OFFICERS

Applications are invited for two appointments of Regional Trials Officers at N.I.A.B. Regional Trials Centres situated at:

(a) School of Agriculture, Sutton Bonington, Loughborough, Leics. Ref. SV/247/N;

(b) A.D.A.S. Experimental Husbandry Farm, Preston Wynne, Hereford. Ref. SV/250/N.

Candidates should possess an honours degree in Agriculture, Agricultural Botany, Botany or Plant Sciences; preference will be given to those who are 26 or over with at least three years postgraduate experience in agriculture or field experimentation.

Salary according to age, qualifications and experience on Grade III—£3,816 to £6,298 p.a. including supplements.

Further particulars and application forms from the Establishments Officer, National Institute of Agricultural Botany, Huntingdon Road, Cambridge CB3 0LE. Telephone: Cambridge 76381 ext 234. Closing date: February 13, 1978. 1112(A)

UNIVERSITY OF RHODESIA FACULTY OF ENGINEERING

LECTURESHIP VACANCIES

The faculty of Engineering has recently been established to provide four-year Honours degrees in Civil, Electrical, Mechanical and Interdisciplinary Engineering, with G.C.E. A-level entry. The Faculty buildings and facilities are fully operative, most professors and lecturing staff are in post, and during 1977, the teaching of the first classes of final (fourth) year students was undertaken.

Applications are invited now for **Lecturer/Senior Lecturer** posts, in the following subject areas. (In each discipline candidates with wide experience and interests will be at an advantage. Areas of special need are shown in brackets).

(a) Civil Engineering: (Geotechnology, Water Engineering, Surveying and Transportation)

(b) Electronic and Power Engineering: (Control Systems, Electromagnetics, Materials)

(c) Mechanical Engineering: (Thermodynamics, Heat Transfer, Solid Mechanics, Fluid Mechanics, Mechanical Design)

(d) Materials Science: (Interdepartmental specialist appointment).

Duties include teaching, research, and assistance with administration.

Minimum qualifications: Good Honours degree (higher degree preferred), plus substantial postgraduate experience. Corporate membership of a professional Engineering Institution desirable.

Salary Scales (Approx. equiv. stg.)
Senior Lecturer £7,352 by £278 to £7,630 by £288 to £7,918 by £298 to £9,706;

Lecturer Grade I £6,675 by £248 to £7,667;

Lecturer Grade II £4,118 by £218 to £5,208 by £248 to £6,448.

Starting salary according to qualifications and experience.

Subject to University permission extra earnings to a specified limit for consultancy may be retained in full. Above this limit they are shared with the University.

Appointments: These may be on permanent pensionable terms or for a fixed term of 1 or 2 years in the first instance. Family passages and allowance towards transport of effects.

One and two-year Contracts: non-pensionable salary as above, plus 10%. Unless born in Rhodesia, expatriates on Contract are exempted from military service. Good rented accommodation is available, some of it fully furnished, close to good, inexpensive Junior and Senior schools and the University Medical Aid Scheme.

Permanent Pensionable Terms: Triennial Contact Visits and Sabbatical Leave with assisted passages overseas; superannuation and medical aid schemes; rented accommodation available for first three years. Installation grant and loan.

Applications: One copy giving personal particulars (including full names, place and date of birth), qualifications, fields of special interest, experience and publications, and giving names and addresses of three referees, should be sent by **February 28, 1978** to: The Senior Assistant Registrar (Engineering), University of Rhodesia, P.O. Box MP. 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. Overseas applicants should send an additional copy to the Association of Commonwealth Universities (Appts), 36, Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained. Applicants should state the earliest date available and also the preferred date.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233-4143) or their nearest British Consular Office.

1064(A)

Pharmacologist

At Fisons we have already established a reputation in the field of allergy research. We are now setting up a small new team to do further innovative research in this area.

We require a Graduate Pharmacologist who would join as a senior member of the new team. If you have a PhD, or are a graduate with a few years' experience, and you have an interest in immunopharmacology then phone Mr P Sheard (0509 66361) for further information, or write to Mr A B Johnston, Fisons Ltd, Pharmaceutical Division, Bakewell Road, Loughborough, Leicestershire, for an application form quoting reference RD1.

UNIVERSITY OF
RHODESIA

FACULTY OF SCIENCE

Applications are invited from suitably qualified persons for the post of:

FACULTY BIOMETRICIAN

Appointment will be at the level of Senior Lecturer or Lecturer. The appointee will be based in the Department of Agriculture and will be required to teach undergraduate courses in Biometry to students of Agriculture and the Biological Sciences. The Biometrician also provides a consulting service for staff and research students in the Faculty.

Salary Scales (Approx. Stg. equiv.):

Senior Lecturer £7,352 by £278 to £7,630 by £288 to £7,918 by £298 to £9,706.

Lecturer Grade I £6,675 by £248 to £7,667.

Lecturer Grade II £4,118 by £218 to £5,208 by £248 to £6,448.

Both permanent pensionable terms and short-term one- or two-year contracts are offered.

Permanent Pensionable Terms: Family passages and allowance towards transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical leave and triennial contact visits with travel allowance. Superannuation and medical aid schemes.

Short-term Contracts: Family passages and allowances towards transport of effects. Assistance with accommodation for persons recruited from outside Rhodesia.

Applications: (6 copies) giving full personal particulars (including full name, place and date of birth, etc.), qualifications, experience and publications and names and addresses of three referees, should be submitted by February 15, 1978 to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. Overseas applicants should send a copy of their applications to Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained.

British subjects considering applying for posts in Rhodesia are urged to consult the Foreign and Commonwealth Office (telephone 233-4143) or their nearest British Consular Office. 1067(A)

UNIVERSITY
OF MELBOURNE
LECTURER
(Limited Tenure)
DEPARTMENT OF
PHYSICAL CHEMISTRY

Applicants with experience in any field of physical chemistry will be considered. Preference may be given to applicants with experience in the application of statistical mechanics to water and aqueous solutions, polyelectrolytes, electrode processes or surfaces. Current research areas within the Department include colloid and surface chemistry, radiation and photochemistry, picosecond spectroscopy, polymer chemistry, vibrational spectroscopy, thermodynamic properties of solutions, electrochemistry and reaction kinetics.

SALARY: \$A14,851 to \$A19,551 per annum.

Further information including details of application procedure and conditions of appointment is available from bourn, Parkville, Victoria, 3052. The Registrar, University of Melbourne, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications referring to Position Number 612 003 should be addressed to The Registrar and close on March 1, 1978. 1118(A)

CSIRO

AUSTRALIA

Research Scientist

Centre for Animal Research
and Development
Bogor, Indonesia

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,000 employees—2,300 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Nutritional Biochemistry (Poultry)

General: The Centre, situated at Ciawi near Bogor in West Java, is a joint activity of the Australian Development Assistance Bureau (ADAB), the Indonesian Department of Agriculture and CSIRO. Its establishment phase will be completed in mid-1978 when the construction of facilities is complete. Currently, it has a staff of about 25 Australians and 200 Indonesians. Total staff, when the Centre is fully operational, is expected to be about 300, including 50 professional scientists.

The research program is broadly aimed at increasing the productivity of the Indonesian livestock industries to meet the increasing demand for food of animal origin. The research will be concerned with the nutrition, reproduction, health and other aspects of the husbandry of chickens, ducks, cattle, buffalo, sheep, goats and pigs.

Supporting the research effort are analytical and veterinary services, mainly concerned respectively with feedstuffs analysis and disease screening and diagnosis for the Centre's experimental livestock.

Duties: A senior scientist is required to lead a research group which is developing nutritionally balanced and economically attractive feedstuffs for the Indonesian poultry industry in collaboration with other research scientists working in this field.

Qualifications: Ph.D. degree in an appropriate field, or equivalent, together with relevant research experience.

Salary: Salary will be the subject of negotiation and will be in the ranges of Senior Research Scientist/Principal Research Scientist: A\$18,171—A\$24,528 p.a. Appointment at a higher level would be considered for a quite outstanding applicant. Overseas service allowances are also payable.

Tenure: 3 years with possibility of extension.

Further information: Further information on the Centre is available on request from the Secretary, CSIRO, P.O. Box 225, Dickson, A.C.T. 2602, Australia.

Applications (in duplicate), stating *FULL* personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 1000/34 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH by 17th FEBRUARY 1978.

Applications in U.S.A. and Canada should be sent to:—

The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON D.C. 20036 U.S.A. 1111(A)

UNIVERSITY OF
GLASGOW
CHEMISTRY DEPARTMENT
(GC-MS UNIT)

Applications are invited for a one-year postdoctoral appointment supported by the Boots Co. Ltd. for a study of the metabolism of a new drug in man. The project will involve open-tubular gas chromatography combined with mass spectrometry, based on LKB9000 and Dupont 21-490F (EI/C1) instruments. Candidates should have experience in gas chromatography and preferably also in GC-MS.

Salary range £3,333 to £3,761 with U.S.S. benefits.

Applications, naming two referees, should be sent to Professor C. J. W. Brooks, Chemistry Department, University of Glasgow G12 8QQ.

In reply please quote Ref. No. 4038M. 1055(A)

UNIVERSITY OF KEELE
VICE-CHANCELLOR

The Council and the Senate of the University of Keele wish to appoint a Vice-Chancellor to succeed Professor W. A. C. Stewart, who will retire on September 30, 1979. Applicants are invited to write in confidence to the Lord Rochester (Pro-Chancellor and Chairman of the Joint Committee of Council and Senate to consider the appointment), c/o the Registry, University of Keele, not later than March 31.

Suggestions on persons suitable for consideration would also be welcome.

The University Council reserves the right to appoint to the post by invitation.

Information about the University and further particulars of the post may be obtained from the Registrar, The University, Keele, Staffordshire ST5 5BG. 1101(A)

UNIVERSITY OF
MELBOURNE
CHAIR OF INORGANIC
CHEMISTRY
(Re-advertised)

The Chair of Inorganic Chemistry, which is one of the three Chairs in the School of Chemistry, is vacant after the appointment of Professor D. R. Stranks as Vice-Chancellor of the University of Adelaide.

Salary: \$A31,248 per annum.

Further information, including details of application procedure, superannuation, travel and removal expenses, housing assistance, and conditions of appointment is available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on March 31, 1978. 1066(A)

A senior overseas position in Horticultural Research for agricultural development in MALAWI £8,300 (part tax free)

As Assistant Principal Agricultural Research Officer at the Hvumbwe Research Station you would conduct procedures affecting agricultural development in this progressive Central African country.

This would be concerned with the production of either vegetables or fruits such as citrus, guavas, mangoes, etc. or tree nuts such as tung and macadamia.

The station provides initial planting material for distribution to farmers, recommends production methods and assists official bodies on produce exporting and markets.

You should have a B.Sc. in Agriculture, Biology, or Botany and have at least 4 years' research experience in the field of agronomy, including horticultural research.

The benefits of low tax and living costs in Malawi can be well worthwhile. In addition, the salary has a tax-free element of £5 682. A terminal gratuity of 25% of total basic salary over the contract term of 30-36 months is also payable tax-free.

Other overseas benefits include free passages, settlement allowances, subsidised accommodation, generous home leave, medical care, etc.

Malawi has a warm sunny climate and friendly people. Its natural scenic beauty contrasts with the modern social and leisure facilities of its expanding cities and townships.

Write for details and application form—quoting Ref. No. MHCL/21, before the closing date 2nd February, 1978—to: 1033(A)

Malawi Malawi High Commissioner,
Recruitment Section,
33 Grosvenor Street, London, W1.

RADCLIFFE INFIRMARY OXFORD

Full-time Research Assistant/Technician required to work in a unit investigating beta cell function in Diabetes. Some experience in histology or animals would be useful but not essential.

Whitley Council scales and conditions. Research grant for 2 years.

Contact Dr R. C. Turner, Department of the Regius Professor of Medicine, Radcliffe Infirmary, Oxford. 1030(A)

CHARLES COULSON SUMMER SCHOOL IN THEORETICAL CHEMISTRY Oxford University from September 10-23, 1978.

Further details from Prof. N. H. March, Theoretical Chemistry Department, 1 South Parks Road, Oxford OX1 3TG. Closing date for applications. May 31, 1978. 1090(A)

LINCOLN COLLEGE (University College of Agriculture) New Zealand LECTURER IN BIOCHEMISTRY

The Council of Lincoln College invites applications for the position of Lecturer in Biochemistry.

Applicants should have a degree in Science or Agricultural Science, and a postgraduate qualification. Preference will be given to those with experience in Agricultural Biochemistry. Duties will include teaching Biochemistry in the course for Bachelor of Agricultural Science, and the appointee will be expected to carry out research in Biochemistry related to Agriculture.

Commencing salary according to qualifications and experience within the range NZ\$10,239 to \$12,543 per annum. At present salaries are supplemented by an 'Interim Special Allowance' of 3.5%.

Travel and removal expenses reimbursed up to specified limits. New Zealand Government Superannuation available.

Conditions of Appointment are obtainable from the Association of Commonwealth Universities, (Appts), 36, Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on **March 6, 1978.** 1076(A)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY RESEARCH ASSISTANT (BIOCHEMISTRY)

A vacancy exists for a Research Assistantship in Biochemistry (male or female) to work on cell mechanisms associated with the regulation and growth and maturation of nervous connections during nervous system development. Previous research experience with tubulin or microtubules or with membrane bound receptors would be an advantage but is not essential. The position is suitable either as a postdoctoral appointment or alternatively for someone wishing to pursue a research programme for a Ph.D. Appointment will be for two years in the first instance. Salary will be on Range 1B (£2,904 to £4,190 per annum), or Range 1A (£3,333 to £5,627 per annum).

Applications, quoting reference 00/8/AI and accompanied by a curriculum vitae and names and addresses of two referees, should be sent to the Registrar, UMIST, P.O. Box 88, Manchester M60 1QD by January 31, 1978. 1049(A)

INFORMATION RESEARCH OFFICER

The Metal Society has been awarded a grant by the British Library to carry out a review of scientific and technical information services in the field of metals and requires a Research Officer for the project.

Basic qualifications required are a knowledge of metals and metals information services and an awareness of the latest techniques for information handling.

The appointment will be for a period of three years: a starting salary up to £5,000 p.a. will be negotiated.

For an application form and for further information write to:

John Vaughan
The Metals Society
1 Carlton House Terrace
London SW1Y 5DB
marking your envelope

**Confidential:
Information Research Officer**

The closing date for receipt of completed applications will be February 24, 1978. 1113(A)

university of wales university college of swansea

Senior Research Assistant

Applications are invited for the vacancy of Senior Research Assistant in the Department of Zoology to work with Dr N. A. Ratcliffe on an N.E.R.C. sponsored project on invertebrate host defence mechanisms and the influence of environmental parameters on these reactions. Candidates should be near to completing or have completed a Ph.D. in Marine Microbiology, Cell Biology or Immunology and should have experience in the use of radioisotopes and basic microbiological techniques. A knowledge of cell separation and fractionation, ecology and/or histochemistry would also be advantageous.

The appointment, which will date from March 1, 1978, or as soon as possible thereafter, will be for one year in the first instance, with the possibility of renewal for a further two years. The commencing salary will be on a scale up to £3,761 per annum plus U.S.S./U.S.D.P.S. benefits.

Further particulars and application forms (2 copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by **Friday, February 10, 1978.** 1124(A)

PORTSMOUTH POLYTECHNIC Biophysics Group SENIOR TECHNICIAN POST 677

The successful candidate will be responsible for the running and maintenance of a Bruker WH 270 MHz plus NMR spectrometer. The spectrometer is used by a large research group working on the structure of chromatin and chromosomal proteins. An interest in and an ability to take part in this research work would be an advantage.

Salary Scale: T3/4 £2,922 to £3,702 plus £473.70 to £512.70 per annum supplement.

Application forms and further details are available from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth or by telephoning Portsmouth 27681 Ext. 317. Closing date Monday, January 30, 1978. 1037(A)

QUEEN ELIZABETH COLLEGE

(University of London)

Campden Hill Road, Kensington, London W8 7AH PHYSIOLOGY DEPARTMENT TECHNICIAN GRADE 4

A vacancy exists for a grade 4 Technician to join a group serving the needs of both teaching and research within the Physiology Department. Candidates should possess O.N.C. equivalent or higher qualifications, and experience in either teaching or research laboratory work would be an advantage.

Salary, including London weighting within range £3,420 (plus L.W. supplement £21.00) to £3,867 (plus L.W. supplement £23.00).

Contact Ms G. M. Dorman for application form: Tel.: 01-937 5411 ext. 499. 1068(A)

THE GRASSLAND
RESEARCH INSTITUTE
Hurley, Maidenhead, Berks.
PLANT PHYSIOLOGIST

A Plant Physiologist is required in the Botany Department to join a small team, led by the Head of Department, investigating the physiology of forage crops in the field. The aim is to provide a rational basis for the improvement of forage production systems by understanding how their productivity is determined by their underlying physiology, and the way management, including method of harvesting, environment and differences in genotype bring about their effect.

Particular emphasis has been placed on crop gas-exchange using an enclosure method. Carbon 14 labelling is also being used. Experience with infra-red gas analysis and radioisotope techniques and other relevant techniques would be an advantage. A sound knowledge of plant physiology and the ability to handle and interpret data are, however, more important.

The Institute is grant aided by the Agricultural Research Council and is an associated Institution of the University of Reading.

Qualifications:- First or upper second class honours in Botany or allied subject.

The appointment will be in the grade of Scientific Officer or Higher Scientific Officer, point of entry depending on qualifications and experience.

Salary:- Scientific Officer £2,592 to £4,032 p.a. including phase I and II pay supplements.

Higher Scientific Officer £3,745 to £4,976 p.a. including phase I and II pay supplements.

At least 2 years postgraduate experience is normally required for appointments to the higher grade. There is a non-contributory superannuation scheme.

Applications to the Secretary by January 31, quoting 3/G/36.

1109(A)

Scientific Officer

Drug Metabolism

Ware

A vacancy has occurred in our Biochemical Pharmacology Department for a biochemist to investigate the metabolism of potential new drugs using both *in vitro* and *in vivo* systems.

Applicants should either be recently qualified Ph.D. graduates with experience of metabolic biochemistry, or good honours graduates with equivalent experience.

The work is conducted in a creative atmosphere in modern laboratories in a pleasant countryside location in Hertfordshire.

The position carries a competitive salary which will reflect the age and experience of the successful candidate. Other benefits include pension and profit sharing schemes, and assistance with relocation expenses where appropriate.

Apply to:

Dr. I. Collins, Personnel Manager, Allen & Hanburys Research Ltd., Ware, Herts.
SG12 0DJ. Telephone Ware 3232.

Allen & Hanburys Limited

1121(A)

Wageningen

The Agricultural University of Wageningen (Netherlands) invites applications for appointment as

Full Professor in Nature Conservation and Nature Management

(due to the imminent retirement of Prof. Dr. M. F. Mörzer Bruyns). Candidates should be able to fulfill the following conditions:

1. substantial experience in the field of scientific backgrounds and applications of Nature Conservation and Nature Management.
2. Qualifications in the field of teaching, education and organisation on an academic level.
3. Willingness and capability for
 - a. effectuation, stimulation and coordination of research.
 - b. making contributions to interdisciplinary activities within and outside the University.
 - c. guiding the integrated approach, necessary for the subject in case.
4. Willingness to cooperate in activities issuing from the Law of University Reform (W.U.B.).
5. Willingness and capability to learn the Dutch language within a brief period; familiarity with French is also highly desirable.

Candidates for this position and those who want to recommend suitable and available persons are asked to contact the "Griffie van de Faculteit der Landbouwwetenschappen", Herenstraat 25, Wageningen, Netherlands within 4 weeks, mentioning all relevant particulars. Letters should be marked "nr. 77-146" on the envelope. Further information may be obtained from the "Griffie" on request.

1083(A)

UNIVERSITY OF SOUTHAMPTON MEDICAL ONCOLOGY (Cell Biologist) Lectureship (or Temporary Lectureship)

Applications are invited for the post of Lecturer (or Temporary Lecturer) in the Professional Medical Oncology Unit. The successful candidate will play an active role in the research activities of the Unit, and will be involved in the day to day running of the laboratories. The ideal candidate will be a cell biologist with an interest in cell membranes and preferably some biochemical experience. Salary scale £3,333 to £6,655 (under review), initial salary will depend upon qualifications and experience.

Further particulars may be obtained from Mr C. W. L. Swann, The University, Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than February 3, 1978. Please quote ref: N/870/A.

1075(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND Canada

DEPARTMENT OF BIOLOGY FISHERIES BIOLOGIST

Applications are invited for a faculty position (rank open), with primary responsibility in the development of a graduate programme (M.Sc. and Ph.D.) in the field of fisheries biology. Preference will be given to candidates with an established background and practical experience in applied fisheries research. Applicants should submit a full curriculum vitae and the names of three referees to Dr G. Robin South, Head, Department of Biology, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X9 by March 20, 1978.

TECHNICIAN required in the DIVISION OF ENTERIC PATHOGENS Colindale, London NW9

Suitable qualifications would include a relevant science degree, F.I.M.L.S., A.I.M.L.S., or H.N.C. in Medical Laboratory Sciences with experience in microbiology. The laboratory studies enterobacterial ecology on a national and international scale and is also concerned with transferable drug resistance in the enterobacteria.

Salary according to age and experience, but not less than £2,184 plus £354 per annum London Weighting, plus £454.50 pay supplements 1 and 2.

Applications with the names of at least two referees to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. Tel. 01-205 7041. 1053(A)

CENTRAL ELECTRICITY RESEARCH LABORATORIES

Kelvin Avenue, Leatherhead, Surrey, KT22 7SE.

is expanding its research on the environmental aspects of electricity generation. The following posts are now available:

TERRESTRIAL ECOLOGISTS

With a higher degree in botanical, agricultural or soil sciences or forestry, to undertake field and experimental studies of plant/soil interactions with atmospheric pollutants. Based at the above location.

Post 1 PROJECT LEADER

With relevant experience and proven ability to lead a small team. Appointment within a salary range rising to £7550 or exceptionally £8350, inclusive of supplements.

Post 2 MEMBER OF TEAM

Appointment within salary ranges rising to £5500 or £6400, inclusive of supplements.

MARINE ECOLOGISTS

Based initially at the CERL Marine Biology Laboratory, Fawley, Nr. Southampton.

POST 3 MEMBER OF TEAM

With postgraduate experience in marine biology, to work on the effects on marine organisms of entrainment in cooling water systems. Appointment within salary ranges rising to £5500 or £6400, inclusive of supplements.

POST 4 MEMBER OF TEAM

With postgraduate experience in ecological modelling, to apply modelling techniques to questions of power station siting. Appointment within salary ranges rising to £5500 or £6400, inclusive of supplements.

Applications, quoting reference RL/75, on standard forms which may be obtained from and returned to the Head of Personnel Services at the above address. Closing date is: 11th February 1978. Application forms may be obtained by telephoning Leatherhead 74488 Extension 329.

1079(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING

Applications are invited for a lectureship in solid state electronics which will be filled from the earliest possible date. Initial salary within the first three points of the lecturers' scale: £3,333, £3,547, £3,761.

Applications and further particulars from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham. Closing date February 3, 1978. Ref: 541. 1107(A)

THE CITY UNIVERSITY DEPARTMENT OF CHEMISTRY

RESEARCH ASSISTANT

required to work on the kinetics of oxygen reduction on semi-conducting oxide/graphite electrode. The appointment will be for one year initially. The research is supported by the Science Research Council. Candidates should have a good honours degree in Chemistry or Materials Science. Salary will be on the scale £2,927 to £4,199 p.a. plus £450 p.a. London Allowance.

Applications, together with the names of two referees should be sent to Dr A. C. C. Tseung, Department of Chemistry, The City University, St John Street, London EC1V 4PB. 1089(A)

UNIVERSITY OF BATH SCHOOL OF BIOLOGICAL SCIENCES LECTURER IN HORTICULTURE

Applications are invited for a lectureship in the Horticulture Group of the School. Candidates should have a degree in Horticulture, postgraduate experience, and preferably a Ph.D. An interest in agronomy (particularly vegetable production) is essential.

Starting salary will be set in the lower part of the range £3,333 to £6,655 p.a.

Application forms and further particulars available from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 77/154 N. Closing date for applications February 20, 1978. 1073(A)

The University of Sheffield DEPARTMENT OF CHEMISTRY POSTDOCTORAL ASSISTANT

Applications are invited for the post of postdoctoral Assistant in an investigation of the synthesis of model enzyme systems related to chorismate synthetase. Tenable up to two years commencing as soon as possible and supported by S.R.C. Salary in the range £3,333 to £3,547 on Range IA with superannuation. Applications with the names of 2 referees should be made to Dr E. Haslam, Department of Chemistry, University of Sheffield, Sheffield S3 7HF. Quote Ref. R.60/G. 988(A)

KENYATTA UNIVERSITY COLLEGE (A constituent College of the University of Nairobi)

Applications are invited for the post of
LECTURER

in the Botany Department

Candidates should have a Ph.D. in Plant Biochemistry or Plant Physiology, with several years University teaching experience. The appointee is expected to teach courses in Plant Biochemistry and Physiology and also conduct research in his/her area of specialisation. Experience in a teacher training institution will be an added advantage. Salary (at present under review) Kf1,800 to Kf3,096 p.a. (Kf1=£1.35 sterling). The British Government may supplement salaries in the range £3,354 to £3,618 p.a. (sterling) for married appointees or £2,184 to £2,400 p.a. (sterling) for single appointees (reviewed annually and normally free of all tax) and provide childrens' education allowances and holiday visit passages. Terms of service include subsidised housing, membership of S.S.S.F. or F.S.S.U. and a non-contributory medical scheme, and family passages. Detailed applications (2 copies) including a curriculum vitae and naming 3 referees should be sent by airmail by February 17, 1978 to the Registrar, Kenyatta University College, P.O. Box 43844, Nairobi, Kenya. Applicants resident in the U.K. should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars are available from either address.

1116(A)

PROFESSOR DEPARTMENT OF MOLECULAR BIOLOGY UNIVERSITY OF GENEVA

Applications should be made before February 28, 1978 to, and information can be obtained from:

Secrétariat de la faculté des sciences de l'université de Genève, quai Ernest Ansermet 20, CH 1211 GENEVE 4 (Switzerland). 1082(A)

MEDICAL RESEARCH COUNCIL UNIT OF CLINICAL PHARMACOLOGY UNIVERSITY DEPARTMENT OF CLINICAL PHARMACOLOGY RADCLIFFE INFIRMARY OXFORD OX2 6HE

Technician required to assist in a research project concerned with the effect of disease and drugs on enzyme activities. Applicants should have H.N.C., degree or equivalent qualifications and be familiar with general biochemical techniques. Experience in enzymology or biochemical pharmacology would be a distinct advantage. Salary will be in the range £2,823 to £4,050 (including supplements), depending upon age and qualifications. Applications with the names of two referees should be sent to the Chief Technician at the above address by January 31. 1058(A)

GUY'S HOSPITAL MEDICAL SCHOOL DEPARTMENT OF MEDICINE TECHNICIAN

required for one year in the first instance to work on a project funded by the Arthritis and Rheumatism Council on the immune response to onco-fetal antigens in rheumatoid arthritis. Salary for qualified Technician not less than £2,982 plus £354 London Weighting. Experience in immunological techniques essential. Starting date April 1. Applications, with the names of two referees, to be sent to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref: D.M.2.

1050(A)

UNIVERSITY OF MELBOURNE CHAIR OF OPTOMETRY

Applications are invited for appointment to the newly established Chair of Optometry.

Salary: \$A31,248 per annum. Further information, including details of application procedure, superannuation, travel and removal expenses, housing assistance, and conditions of appointment, is available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on March 31, 1978. 1069(A)

I.L.R.A.D.

International Laboratory for Research on Animal Diseases invites applications from qualified candidates for the following position:—

IMMUNO-CHEMIST

I.L.R.A.D. is recruiting for a core or visiting scientist's position in Immuno-chemistry for immediate employment. I.L.R.A.D. is a modern research institution located in Nairobi, Kenya, and has an international staff. The Laboratory is conducting research on trypanosomiasis and theileriosis, two important diseases that constrain livestock production for food and other uses in many developing countries. Research at I.L.R.A.D. offer the opportunity to work on meaningful problems with international implications, to conduct investigations at headquarters in Nairobi and elsewhere and to relate to a group of scientists carrying out multi-disciplinary activities of broad scope.

QUALIFICATIONS:

Minimum 3 years postdoctoral (or equivalent) experience. Solid experience with current techniques in molecular immunology (protein purification, detection and characterisation of cell surface antigens, radioimmunoassay, antigen-antibody interactions, lectin technology, gel technology, antibody function etc.). The candidate should also be familiar with and conversant in several aspects of cellular immunology. Scientists interested in being considered for this post should provide a current curriculum vitae (including a synopsis of training, research experience and publications). Three referees who can be contacted in support of their candidacy should also be included.

TERMS

Salary—Negotiable

Other include Housing allowance, commutation allowance, pension scheme and medical aid scheme, etc.

This information should be sent to:—

The Director,
I.L.R.A.D.,
P.O. Box 30709,
NAIROBI,
Kenya to reach him not later than February 6, 1978. 1110(A)

Technical Services

**TECHNICIAN
(HORTICULTURE)**

Salary: £2,529 to £2,853

(plus supplement range: £454.08 to £470.28)

To carry out horticultural duties and give general assistance in the running of Rumleigh Experimental Station particularly the growing and propagation of plants in the open and under glass for teaching and research projects.

The Experimental Station is situated at Bere Alston, 14 miles from the Polytechnic (City Centre).

Applicants should possess a current driving licence, an O.N.C. in Horticulture or equivalent and at least 3 years' appropriate experience.

Application forms, to be returned by February 10, 1978, can be obtained with further particulars from the Personnel Officer. 1072(A)

**NATIONAL VEGETABLE
RESEARCH STATION
SOIL SCIENTIST**

A SOIL SCIENTIST is required for studies on the soil aspects of site to site variations in yield of field vegetables, the work involving the development of theories and quantitative models for differences in productivity between soils and testing these in field experiments. The appointment will be in the Grade of Higher Scientific Officer (£3,745 to £4,976) or Senior Scientific Officer (£4,707 to £6,300) including supplements.

Non-contributory superannuation scheme.

First or Upper Second Class Honours Degree. At least two years research in Agronomy, Soil Science or other relevant scientific subject is required for appointment as H.S.O.; for appointment as S.S.O. evidence will be required of the candidate's ability to carry out research at this level, preferably by reference to published papers. An adequate mathematical background is essential.

Full particulars and application form from the Secretary, National Vegetable Research Station, Wellesbourne, Warwick. Closing date for receipt of applications is February 9, 1978. 1038(A)

**RESEARCH ASSOCIATE
IN ATMOSPHERIC
SCIENCE (AERONOMY)—**

The Department of Atmospheric and Oceanic Science of the University of Michigan has a post-doctoral research position available in the area of terrestrial and planetary aeronomy. This position involves analysis and interpretation of data obtained from a variety of space missions (e.g. Pioneer-Venus, Voyager, Dynamics Explorer, etc.). This work is to be carried out in collaboration with Professors T. M. Donahue and A. F. Nagy. Send resumes to: University of Michigan, Office of Professional and Administrative Staff Services, 1020 "NN" L. S. and A. Building, Ann Arbor, Michigan 48109. A non-discriminatory, affirmative action employer. 1095(A)

**MEDICAL RESEARCH
COUNCIL
TOXICOLOGY UNIT**

Junior Technician or young Technician required to assist in biochemical laboratory systems of mammalian liver. Qualifications: O.N.C. (Applied Biology) or equivalent for Junior grade or H.N.C. (or equivalent) for Technician grade. Salary within the range of £1,571 to £2,298 plus London Weighting and Supplements or £2,511 to £3,738 plus London Weighting and Supplements. Grade and salary according to age, qualifications and experience (preference given to candidates with experience in biochemical techniques).

Apply in writing to The Director, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF. 1057(A)

**THE UNIVERSITY OF
MANCHESTER
RESEARCH ASSOCIATES
IN GERIATRIC MEDICINE**

There are vacancies for an Electron Microscopist (appointment for up to 3 years) and a Mechanical Engineer (appointment for up to 2 years). These appointments, preferably post-doctoral, are as part of a new team developing research into the aging bladder and the problems of incontinence. Salary range: £3,333 to £5,015 p.a. The work will be carried out in the research laboratories of the Department of Geriatric Medicine at the University Hospital of South Manchester, Nell Lane, Manchester M20 8LR, under the overall direction of Professor J. C. Brocklehurst, from whom further details may be obtained. 1060(A)

**UNIVERSITY OF LONDON
Canterbury Hall of Residence**

The University requires to fill the post of

BURSAR

at this Hall of Residence for 222 women students, becoming vacant owing to retirement on August 1, 1978.

Candidates should possess appropriate qualifications and experience preferably in the running of a University Hall of Residence or similar establishment.

Salary is on the scale £3,182 by £204 to £4,160 (subject to review) plus £450 London Allowance and free board and residence.

Further particulars are available from Mrs Debbie Croucher, Personnel Section, Room 223, University of London, Senate House, Malet Street, London WC1E 7HU. Closing date for receipt of applications is February 17, 1978. 1117(A)

Hydrologist

for resource data in MALAWI

up to £7,865 (part tax free)

This interesting position calls for a Hydrological Data Processing specialist, to handle all water resource data as part of the national Development Programme of this progressive Central African country.

You would be responsible to the Principal Hydrologist for

- supervising and developing an existing DP system
- training DP staff
- publishing annual data in acceptable international format
- reviewing and assessing incoming hydrological data
- updating storage/retrieval of past data
- analysing data for water resource projects

You should have a degree in Mathematics, Civil Engineering, Geography or a related discipline, plus a sound knowledge of hydro-meteorological practices. At least 3 years' experience of modern DP methods—using COBOL and/or FORTRAN—is essential and experience of ICL job control language would be advantageous.

The salary has a tax-free element of £5,532. A terminal gratuity of 25% of total basic salary over the 30-36 months contract is also payable tax free.

Other overseas benefits include free passages, settlement allowances, subsidised accommodation, generous home leave, medical care, etc.

Malawi has a warm sunny climate, a friendly people and its natural scenic beauty contrasts with the modern social and leisure facilities of its expanding cities and townships.

Write for details and application form—quoting Ref. No. MHC/10, before the closing date 2nd February, 1978—to:

1031(A)

Malawi Malawi High Commissioner,
Recruitment Section,
33 Grosvenor Street, London, W1.

**UNIVERSITY OF
ABERDEEN****SENIOR LECTURER IN
AGRICULTURAL
BIOCHEMISTRY
(Animal Nutrition or
Biochemistry)**

Applications are invited for the above University post in the School of Agriculture. Candidates should have an honours degree in Biochemistry, Agricultural Biochemistry or Chemistry, and substantial post-graduate research experience in either Animal Nutrition or Animal Biochemistry.

Salary on scale £6,443 to £7,951 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by February 11, 1978. 1987(A)

**DEPARTMENT OF PHYSICS
ASSISTANT
PROFESSORSHIP**

Subject to adequate funding, a position may become available July 1, 1978 in one of the following fields

**QUANTUM OPTICS
BIOPHYSICS**

Salary depends on qualifications. The closing date for applications is March 31, 1978.

Exceptional candidates in other fields may be considered.

All correspondence should be addressed to:

Professor Luis de Sobrino,

Chairman,

Appointments Committee,

Department of Physics,

The University of British

Columbia,

2075 Westbrook Place,

Vancouver, British Columbia,

Canada V6T 1W5. 823(A)

THE UNIVERSITY OF BRITISH COLUMBIA

In anticipation of increased activity in coal exploration, production and utilization within the Province of British Columbia, the University of British Columbia, a government funded institution which provides instruction and research opportunities to 23,000 students, is expanding its coal activities. A new coal research laboratory is scheduled for completion in 1978 and the following faculty appointments are expected to be made in August, 1978.

Within the Department of Mineral Engineering:

Coal Processing—Working in conjunction with three mineral processing faculty members, the appointee can expect to lead the coal processing activities of the department by providing appropriate instruction and research direction to undergraduate and graduate students.

Applicants are expected to be holders of advanced degrees who, through participation in coal-processing plant design and operation, and/or coal processing research, are well versed in current technology.

Mine Services—In collaboration with three mining engineer faculty members, the appointee will engage in the teaching and research aspects of mine ventilation, materials handling systems, and the control of dust and noxious gases. The appointee will be a graduate engineer who, through appropriate underground mining experience, is conversant with modern practice in the specific fields mentioned above. Coal mining experience is a decided asset for this appointment.

Rock Mechanics—The appointee will hold an appropriate advanced degree and will be oriented to the measurements of in-situ rock stress distributions and the design of underground openings in strata-bound sequences. In cooperation with three mining engineer faculty members, the appointee will be responsible for undergraduate instruction and graduate studies in applied rock mechanics. Currently the department possesses a variety of rock properties measurement equipment and has direct access to an extensive computer facility.

Within the Department of Geological Sciences:

Coal Geologists—The department is seeking a geologist who will develop a coal geology program that integrates with the coal activities in Mineral Engineering. The appointee will be involved in teaching coal geology, the supervision of graduate students, and a research program in geologic aspects concerned with mine development, such as structure, stratigraphy correlation, petrology, and geo-statistics. A Ph.D., in hand or pending, and field experience in coal geology are essential. It is expected the appointment will be made at the Assistant of Associate level.

Applicable salary ranges are as follows:

Assistant Professor	\$20,000—\$27,000 per annum
Associate Professor	\$27,000—\$32,000 per annum
Full Professor	\$30,000—\$35,000 per annum

Enquiries, or applications accompanied by a full curriculum vitae and the names of three referees, should be directed as follows:

a) for positions within Mineral Engineering

The Head,
Department of Mineral Engineering,
University of British Columbia,
VANCOUVER, B. C., Canada V6T 1W5

b) for the position within Geological Sciences

Dr. W. H. Matthews
Chairman, Coal Committee
Department of Geological Sciences
University of British Columbia,
VANCOUVER, B. C., Canada

This announcement should not be construed as a commitment by U.B.C. to make appointments in rigid adherence to the above descriptions. 926(A)

INSTITUTE OF CHILD HEALTH NEONATAL DEPARTMENT POSTDOCTORAL RESEARCH ASSISTANT IN BIOCHEMISTRY

Applications are invited for the post of Research Assistant to take part in a new project on control of fetal lung development. The person appointed will continue and extend current studies on the cellular composition and biochemical maturation of pathological and experimental lung tissue. Applicants should have postgraduate laboratory experience and will be expected to hold a Ph.D. or M.Sc.. The appointment will be for 3 years.

Starting salary in the range £3,805 to £4,649 including London Weighting.

Full details and application forms available from Dr J. S. Wigglesworth, Department of Paediatrics and Neonatal Medicine, Hammersmith Hospital, Du Cane Road, London W12 0HS. 1108(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF EARTH SCIENCES RESEARCH FELLOW

A vacancy exists in the above Department for a

with Ph.D. and with experience of high pressure/temperature apparatus and techniques, to determine experimentally carbonate equilibria in the system $\text{CaCO}_3\text{-MgCO}_3\text{-FeCO}_3\text{-MnCO}_3$ under typical metamorphic conditions.

The appointment is for a fixed term of two years from May 1, 1978 or as soon as possible thereafter. Salary on the IA Scale for Research and Analogous Staff £3,761 to £3,975 (under review). Applications naming three referees should be addressed to Professor J. C. Briden, Department of Earth Sciences, The University, Leeds LS2 9JT, from whom further particulars may be obtained, as soon as possible and in any case not later than March 31, 1978. 1097(A)

THE UNIVERSITY OF MANCHESTER DEPARTMENT OF MEDICAL BIOPHYSICS RESEARCH ASSOCIATE IN WOLFSON IMAGE ANALYSIS UNIT

Applications are invited for this post in a group developing image analysis techniques for application to problems in clinical medicine, medical research and industry. The work involves not only a considerable intellectual challenge but also close collaboration with industry to produce image analysis solutions in marketable form.

Candidates should have research or development experience and probably a physical science or mathematical background. The project aims at exploiting MAGISCAN, a computer based image analysis system. This means that computer programming will be involved but a wider problem solving ability is sought.

The post is tenable initially for up to two years. Initial annual salary range: £3,333 to £5,015. Superannuation.

Applications should be made by January 31, Dr C. J. Taylor, Department of Medical Biophysics, Stopford Building, The University, Manchester M13 9PT. 1061(A)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF SOCIAL MEDICINE

A graduate is required to take part in an epidemiological study of multiple primary tumours at Birmingham and West Midlands Regional Cancer Registry. Applications are invited from biologists with experience in statistical methods with a knowledge of Fortran programming, but other graduates with suitable experience would be considered.

The appointment is on the Research Associate IB grade (£2,904 to £4,190). Initial salary will depend on age and experience.

Applications should be sent to The Assistant Registrar, The Medical School, Birmingham B15 2TH, by February 10, 1978. 1071(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING Applications are invited for a LECTURESHIP

in solid state electronics which will be filled from the earliest possible date. Initial salary within the first three points of the lecturers' scale: £3,333, £3,547, £3,761.

Applications and further particulars from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham.

Closing date: February 3, 1978. Ref: 541. 1122(A)

UNIVERSITY OF WOLLONGONG Australia

SENIOR LECTURER/LECTURER
IN COMPUTING SCIENCE (A)
(Tenurable Appointment)
LECTURER IN COMPUTING
SCIENCE (B)
(Limited Term Appointment
of up to 4 Years)

Applicants should have a higher degree in Computer Science and some experience in research and/or teaching. The successful applicants will participate in the development of the Computing Science course program at undergraduate and graduate level. It is anticipated, subject to the approval by the Council of the University, that Computing Science activities (currently part of the Mathematics Department) will form the Department of Computing Science in the near future.

Currently active research areas are: portability of operating systems (UNIX in particular); interactive languages; databases and text searching algorithms. A Computing Science laboratory with 8 terminals time sharing an Interdata 7/32 computer is available for teaching and research.

Further information may be obtained from Professor J. Reinfelds, in the University.

Commencing salary according to qualifications and experience, will be within one of the ranges:—Senior lecturer \$A19,676 to \$A22,955; Lecturer \$A14,632 to \$A19,262.

For details of appointment write to the Bursar, The University of Wollongong, Box 1144, P.O. Wollongong, N.S.W., 2500, Australia (please specify position A or B or both), or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Closing date March 1, 1978. 1070(A)

DEPARTMENT OF NUTRITION AND FOOD SCIENCE MASSACHUSETTS INSTITUTE OF TECHNOLOGY FACULTY POSITION

The Department, a large multi-disciplinary teaching and research unit with activities in all principal areas of nutrition and food science is seeking an applicant to fill the following faculty position:

An M.D., with research training and preferably with a Ph.D. degree, and experience and a major interest in human and clinical nutrition. The appointee will be expected to teach graduate level courses concerned with human and clinical nutrition, to develop a vigorous research programme and become actively involved in the research programmes of the M.I.T. Clinical Research Center.

The appointment will be at the Assistant or Associate Professor rank depending upon the qualification of the successful applicant.

Curriculum vitae, together with representative publications and the names of five referees should be submitted before February 1, 1978 to: Dr V. R. Young, Chairman Search Committee, Room 56-331, Massachusetts Institute of Technology, Cambridge M.A. 02139, U.S.A.

M.I.T. is an Equal Opportunity Employer. Representatives of minority groups are urged to apply. 830(A)

Microbiology

The Department of Microbiology, Schools of Medicine and Dentistry, with the Diabetes Research and Training Center and the Institute of Dental Research, respectively, invite applications from individuals with research interests in:

1. Regulation of Viral Protein Synthesis
2. Oral Microbiology — Immunology.

Candidates should have a Ph.D. or equivalent terminal degree, expect to develop a strong research program, and participate in the education of graduate and professional students. A curriculum vitae, relevant reprints, description of research interests, and three letters of reference should be forwarded to: Dr Kenneth J. Roozen, Vice-Chairman, Department of Microbiology, The University of Alabama in Birmingham, Birmingham, Alabama 35294, U.S.A., not later than March 1, 1978. An affirmative action/equal opportunity employer. 1100(A)

ST BARTHOLOMEW'S HOSPITAL

London EC1A 7BE

RESEARCH ASSISTANT/ TECHNICIAN

DEPARTMENT OF
MEDICAL MICROBIOLOGY

Applications are invited from Technicians and Graduates (M.Sc./Ph.D.) for a position available for 1 year in the first instance, but with a possibility of renewal for a further 2 years, to work on a research project on the serology of anaerobic bacteria and relationship to pathogenicity in diagnostic medical microbiology. Applicants with training and/or experience in serological techniques, microbiology and/or immunology will be considered. The work will involve the preparation and purification of microbial antigens, preparation and purification of antisera and immunofluorescent techniques.

Salary according to experience on the scale £3,333 to £5,627 plus London weighting plus earning supplements.

Applications stating age, qualifications, present post, past experience, and the names of two referees, should be sent to the Personnel Department within three weeks of the date of publication, quoting reference RP 90/77.

City & Hackney Health District—part of The City & East London AHA(T). 1052(A)

SEARCH FOR EXTRASOLAR PLANETS

An anticipated new grant includes funds available as of February 1978 for a research associate who would participate in a search for low-mass companions of solar-type stars using a recently constructed Digicon radial velocity meter with Fabry-Perot wavelength calibration. Duties of the position will include telescopic observations, their reductions and interpretation, and a continuous improving of the instrument and computer reductions to minimise the errors of radial and rotational velocities. The candidate must have a doctorate and experience with computer programming, advanced instrumentation, and astrophysical observations. Please send resume and three letters of recommendation from recognised astronomers to Dr K. Serkowski, Lunar and Planetary Laboratory, University of Arizona, Tucson, Arizona 85721. An equal opportunity/Affirmative Action/Title IX, Section 504 Employer. 1094(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

MICROBIOLOGICAL CHEMISTRY
RESEARCH LABORATORY

POSTDOCTORAL RESEARCH ASSOCIATES

Applications are invited for two posts of Postdoctoral Research Associates in a group studying the biosynthesis and function of teichoic acids in bacterial cell walls and membranes. The work includes either structural or metabolic aspects in this rapidly developing field and experience in either biochemistry or microbiology would be appropriate.

The appointments are for three years Salary in range 1A £3,333 to £5,627 per annum, plus superannuation benefits. Tenable from February 1, 1978 or by arrangement. Applications with curriculum vitae and the names of two referees to Professor Sir James Baddiley, F.R.S., Microbiological Chemistry Research Laboratory, The University, Newcastle upon Tyne NE1 7RU. 1062(A)

FRESHWATER BIOLOGICAL ASSOCIATION

River Laboratory

ZOOLOGIST

required to assist in team project on Biological Classification of Rivers. Experience in river invertebrate taxonomy and ability to work methodically on samples essential, interest in computing desirable. Three-year contract equivalent to Scientific Officer in Civil Service. Gross salary within the range £2,592 to £4,032.

Full details and application form from the Secretary, Freshwater Biological Association, River Laboratory, East Stoke, Wareham, Dorset BH20 6BB. Closes February 10. 1081(A)

UNIVERSITY COLLEGE OF NORTH WALES

Applications are invited for the post of
LECTURER IN ZOOLOGY

The appointment will be on the scale: £3,333 to £6,655 per annum (under review).

Applications (two copies), giving full details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for the receipt of applications: February 28, 1978. 1123(A)

ELECTROCHEMIST

with experience in anodic synthesis and other preparative electrochemical reactions required for new project for chemical synthesis. Give full details of past experience in the above fields. Maybridge Chemical Co. Ltd., Tintagel, N. Cornwall. 1096(A)

AN FORAS TALUNTAIS

DAIRY AND FOOD PROCESSING RESEARCH

Applications are invited for two posts in the Dairy Technology Department, Moorepark Research Centre, Fermoy, Co. Cork. Research will be mainly concerned with Unit Process Evaluation and Development and the subsequent introduction of processes at Industrial Level.

ESSENTIAL: An Honours University degree, or equivalent, in Food or Dairy Engineering or other appropriate discipline.

DESIRABLE: Relevant research experience, particularly in dehydration or fermentation.

Commencing salary and level of appointment will depend on qualifications and experience. Marriage and Childrens' allowances. Non-contributory pension scheme and provision for Widows' and Orphans' pensions.

Application forms and further particulars may be obtained from The Personnel Department, An Foras Taluntais, Headquarters, 19 Sandymount Ave., Dublin, 4. (Tel: 688188). Latest date for receipt of completed application forms Friday, February 10, 1978. 1041(A)

Microscopist

Redland Technology serves the multi-national Redland Group of Companies which is concerned with the manufacture of building and construction materials.

A wide variety of interesting research and development projects are currently in progress at the New Technology and Product Development Centre at Horsham, where a vacancy exists for a person experienced in the use of optical and/or electron microscopes and in carrying out the associated specimen preparation techniques. Duties will include responsibility for the optical microscope facility and provision of a service to the technical staff at the centre and in the various manufacturing divisions.

Day release for further study and training schemes are in operation. Salary will be on a scale up to £4,000 depending on age, qualifications and experience. Please apply to Dr. S. E. Horsley, Redland Technology, Graylands, Horsham, W. Sussex. RH12 4QG. 1048(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND DEPARTMENT OF GEOLOGY

The Department of Geology invites applications for three faculty positions in **Sedimentology and Marine Geology** with special reference to the Labrador continental margin (subject to the availability of funds).

One appointment will be a regular faculty position at a salary and rank commensurate with qualifications and experience. The appointee will direct and participate in the activities of a research group working in the following specialities: Mesozoic and Cenozoic clastic sedimentology, clay mineralogy, sedimentary geochemistry and micropaleontology. Applications from suitably qualified candidates with working experience in the petroleum industry will be especially welcome.

Two appointments will be at the rank of Assistant Professor (Research) and will be for a two-year term in the first instance. Applicants should have proven research ability in one (or more) of the specialist fields listed above.

Applications for all three positions, which must include a detailed curriculum vitae and the names and addresses of three referees, should be sent by March 31, 1978 to: Dr David Skevington, Head, Department of Geology, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X5. 1077(A)

FRANK HORNE AWARDS

A Studentship and grants for research or study of seeds, plants or crops in relation to the agricultural and horticultural industry are available for 1978/79. Details and application forms from K. C. Batchelor, National Institute of Agricultural Botany, Huntingdon Road, Cambridge, England. 1099(F)

THE UNIVERSITY OF LEEDS DEPARTMENT OF RADIOTHERAPY

Applications are invited from graduates with good honours degree in biological sciences for a

POSTGRADUATE RESEARCH STUDENTSHIP

The project will involve a cellular kinetic and quantitative microscopical study of the action of drugs and radiation on experimental tumors.

Applications giving a full curriculum vitae, including the names and addresses of two academic referees, should be forwarded to Professor C. A. F. Joslin (Regional Radiotherapy Centre, Cookridge Hospital, Leeds LS16 6QB) from whom further details are available. 1040(F)

The Macaulay Institute for Soil Research, Aberdeen

RESEARCH STUDENTSHIPS

Applications are invited from students who hold or expect to hold upper second class honours degrees in the appropriate subject for Ph.D. studentships at the standard S.R.C./A.R.C. rates for work in the following areas:

Spectroscopy (E.S.R. and Laser)
Physical Chemistry (Sorption and Thermochemistry)
Organic Chemistry (Enzymes)
Plant Physiology (Calcium translocation)

Candidates, who must have British nationality, should submit applications to Professor T. S. West (Director), The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ. 987(F)

BRUNEL UNIVERSITY DEPARTMENT OF NON-METALLIC MATERIALS RESEARCH STUDENTSHIP

Applications are invited for a postgraduate research post tenable from March 1, 1978, for three years. The studentship is sponsored by the Blue Circle Group to study the development and the mechanical behaviour of Polymer Cements.

Interested persons with a good first degree in Materials or Polymer Science or other relevant discipline should apply to Dr K. A. Hodd, Department of Non-Metallic Materials, Brunel University, Uxbridge, Middlesex. 1126(F)

HERIOT-WATT UNIVERSITY DEPARTMENT OF BREWING AND BIOLOGICAL SCIENCES RESEARCH ASSOCIATESHIP

Applications are invited from graduates in microbiology for the post of Research Associate in the Department of Brewing and Biological Sciences, Heriot-Watt University. This is a joint project with the University of Newcastle upon Tyne. It is funded by the S.R.C. for a period of three years under the direction of Drs F. G. Priest and M. Goodfellow and involves a polyphasic taxonomic study of the genus *Bacillus*. The successful applicant may be able to register for a higher degree. The initial salary is £2,904 per annum (under review).

Informal enquiries may be made to Dr F. G. Priest (Tel. 031-225 8432 Ext. 307).

Application forms are available from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX to whom they should be returned by February 2, 1978. 1032(O)

UNIVERSITY OF OXFORD

Applications are invited from Biochemists, Geneticists and Zoologists for a three year postdoctoral assistantship with a group investigating the genetic control of collagen expression, particularly in somatic cell hybrids. The project, which is financed by the Medical Research Council, operates between the Department of Pathology, Radcliffe Infirmary, and the Genetics Laboratory of the Department of Biochemistry.

The salary range is £3,761 to £4,190 per annum. Closing date: February 28, 1978.

Curriculum vitae and the names of two referees should be sent to Dr B. Sykes, Department of Pathology, Radcliffe Infirmary, Oxford, from whom further details are available. 1115(P)

GRADUATE ASSISTANTSHIPS

are available for well qualified pre-doctoral students in Geophysical Fluid Dynamics, particularly in the area of computer and laboratory modelling of variations in the climate. A strong background in mathematics and physics is needed but prior training in a geophysical discipline is not necessary. Minorities and women are especially encouraged to apply. Write to Director, Geophysical Fluid Dynamics Institute, 18 Keen Building, Florida State University, Tallahassee, Florida 32306. 784(P)

THE UNIVERSITY OF BRITISH COLUMBIA DEPARTMENT OF CHEMISTRY GRADUATE TEACHING ASSISTANTSHIPS

Graduate Teaching Assistantships are available for candidates with high academic records who wish to pursue further studies towards the M.Sc., and Ph.D. degrees in chemistry. Excellent research facilities are available in all areas of modern chemical science, ranging from bio-inorganic chemistry to chemical physics. The minimum stipends including summer research assistantship will be \$6,120.00 per annum for first year and \$6,500.00 for students entering with a Master's Degree. The stipends are current under review. In addition, many special merit awards are made to those Graduate Teaching Assistants who show excellence in their performance of their duties. Numerous graduate scholarships are also available for students with outstanding academic records.

Application forms and further particulars may be obtained from the undersigned:

MASSEY UNIVERSITY

Palmerston North, New Zealand

POST DOCTORAL FELLOWSHIPS

Applications are invited for Postdoctoral Fellowships tenable in an Department of the University.

The academic activities of the University are grouped under the following faculties and schools.

Opportunities for study and research are available in the following field

AGRICULTURAL AND HORTICULTURAL SCIENCE

Agricultural economics and marketing, Farm Management, Agricultural Engineering, Agronomy, Animal Science (dairy, sheep, beef, pigs), Horticultural Science and Plant Health, Poultry Science, Soil Science.

BUSINESS ADMINISTRATION

Agricultural Business, Business Studies, Data Processing, Economic Financial Management and Accounting, Marketing, Personnel Administration

FOOD SCIENCE AND BIOTECHNOLOGY

Food Technology, Biotechnology (i.e. processing of Biological Materials Industrial Management and Engineering, Industrial Management and Industrial Mathematics.

HUMANITIES

English, History, French, German, Philosophy.

SCIENCE

Biochemistry, Biophysics, Botany, Chemistry, Genetics, Microbiology, Zoology.

SOCIAL SCIENCE: Applications from scholars in any of the usual Social Science Disciplines will be welcomed, but particular preference may be given to those interested in Educational Sociology, Human Geography and/or Planning, Mathematics, Social and Applied Psychology, and Economics.

VETERINARY SCIENCE

Physiology and Anatomy, Veterinary Pathology and Public Health Clinical Sciences.

Information concerning the research activities of the departments associated with these groups are given in the University Calendar. Interested applicants are advised to write to the Head of the appropriate department in the course of preparing an application.

A Fellowship will be tenable for one year, with possible extensions, and carries an emolument of NZ\$8,500. Travelling expenses up to NZ\$1,500 may be provided.

Further details of the position and of the University, together with conditions of appointment and information to be supplied by applicants, may be obtained from the Association of Commonwealth Universities (Apsu), Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **February 17, 1978.**

1120(E)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

DEPARTMENT OF
BIOCHEMISTRY AND
SOIL SCIENCE

POSTDOCTORAL RESEARCH FELLOWSHIP PHYTOCHEMISTRY ECOLOGICAL

Applications are invited for a N.E.R.C. Postdoctoral Fellowship to work in collaboration with Dr R. G. Wyn Jones on the accumulation of organic solutes, particularly nitrogenous compounds in halophytic and xerophytic plants.

Experience in the isolation and characterisation of small molecular weight organic compounds and an interest in plant ecology and taxonomy will be highly desirable. The appointment is for two years and will commence on May 1, 1978, at a salary of £3,333 per annum plus superannuation.

Applications (two copies), together with the names and addresses of two referees should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, by February 25, 1978, from whom further details may also be obtained. 1088(E)

UNIVERSITY OF WARWICK

POSTDOCTORAL RESEARCH FELLOW

in

Biological Sciences

Applications are invited for a Postdoctoral Fellowship within the Chloroplast Development Research Group. This three-year post, supported by the S.R.C., is concerned with the study of photosynthetic membrane formation in plants, with special reference to the control of synthesis of the light-harvesting chlorophyll *a/b* binding protein by light. Experience with *in vitro* translation systems would be a distinct advantage. Initial salary will be up to £3,761 p.a. on the Range 1A scale; £3,333 to £5,627 p.a. (under review), depending on age and experience.

Further details and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 24/R/78.

Closing date for receipt of applications February 13, 1978. 1098(E)

QUEEN MARY COLLEGE

University of London

CHEMISTRY DEPARTMENT

Applications are invited for a Postdoctoral

RESEARCH FELLOWSHIP

in Organic Chemistry to investigate the porphyrin-N-oxides in collaboration with Professor R. Bonnett. The post would suit candidates well grounded in heterocyclic chemistry, but with an interest in biochemistry. The post is tenable for two years from July 1, 1978 (or as soon as possible thereafter). Initial salary in range (under review) £3,805 to £4,019 p.a. (including London Allowance).

Please apply by letter, enclosing curriculum vitae and names and addresses of 2 referees, to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS. 1036(E)

ONTARIO CANCER INSTITUTE POSTDOCTORAL FELLOWSHIP

available to join a group working on the genetics and molecular biology of murine oncornaviruses and erythropoiesis. Candidates should be about to graduate in virology, biochemistry or cell biology in the spring or summer of 1978. Applicants should send curriculum vitae with three letters of references to Drs T. W. Mak or A. Bernstein, Division of Biological Research, Ontario Cancer Institute, 500 Sherbourne St., Toronto, Ontario, Canada M4X 1K9. Stipend will be \$11,600 to \$12,700 annually. 1093(E)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES DEPARTMENT OF DEVELOPMENTAL BIOLOGY RESEARCH FELLOW

A Research Fellowship is available for two years, with possible extension, in preparative protein biochemistry to investigate the plant photoreceptor, phytochrome. Research is in progress to separate this protein in pure, native form. The appointee would take up this work and continue with the characterisation of phytochrome and with immunological studies on it.

CLOSING DATE: FEBRUARY 28, 1978.

DEPARTMENT OF NEUROBIOLOGY RESEARCH FELLOW

The position of Research Fellow is available in the Department of Neurobiology. The major requirement is that the applicant has the ability to sustain imaginative research programs in critical areas of invertebrate neurobiology.

The Department's present interests cover arthropod vision and hearing, but it wishes to diversify and any invertebrate neurobiologist with a Ph.D. degree is invited to apply.

Appointment for three years in the first instance with possibility of extension to five years.

CLOSING DATE: FEBRUARY 28, 1978.

SALARIES: Salary on appointment to the posts will be in accordance with qualifications and experience within the range: Research Fellow \$A14,851 to \$A19,426 p.a. Current exchange rates are \$A1 : 60p : \$US1.13.

OTHER CONDITIONS: Superannuation benefits are available. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Apspts), 3 Gordon Square, London WC1H 0PF. 1039(E)

UNIVERSITY OF MELBOURNE POSTDOCTORAL RESEARCH FELLOWSHIP

in the

DEPARTMENT OF
MICROBIOLOGY

Applications are invited from Ph.D. graduates for the above-mentioned position which is funded by the Australian National Health and Medical Research Council and is available from January 1978 or soon after. The candidate will participate in a programme to develop continuous cell lines derived from immune lymphocytes. Previous experience in cytology, especially in the use of fusion hybrid techniques, would be an advantage. The position is available for two years with the possibility of renewal.

Salary: \$A17,279 per annum.

Enquiries will be welcomed by Dr W. Boyle, Department of Microbiology, University of Melbourne, Parkville, Victoria 3052, Australia. Applications referring to position number 526 355 should be addressed to The Registrar, University of Melbourne, Parkville, Victoria 3052. 1078(E)

MENTAL HEALTH FOUNDATION

8 Wimpole Street . London W1M 8HY

Telephone: 01-580 0145

Announces that

the Sir Geoffrey Vickers Lecture entitled

THE STUDY OF RELATIONSHIPS— IN QUEST OF A SCIENCE

will be given by

Professor Robert Hinde

M.R.C. Unit on the Development and Integration of Behaviour

Cambridge

at the

Middlesex Hospital Medical School, Cleveland Street, London W1 on Wednesday, February 8, 1978 at 5.30 p.m.

The Chair will be taken by

MR DUNCAN DEWDNEY, C.B.E., B.Sc.,
Chairman, Research Committee of the Foundation

All practitioners and students of medicine and its basic sciences are cordially invited to attend. Please apply for an invitation card to the

Secretary (N),

Research Committee,

Mental Health Foundation.

(There are no parking facilities)

1106(K)

UNIVERSITY COLLEGE GALWAY, IRELAND

DEPARTMENT OF PHYSICS

Applications are invited for a

POSTDOCTORAL

FELLOWSHIP

or

RESEARCH

ASSISTANTSHIP

for work on a project involving an investigation of the role of lead (and possibly other pollutants) in motor vehicle exhaust in the nucleation of ice in the atmosphere.

Support for the post which is tenable until the end of 1978 will come from the National Science Council.

Salary will be payable at the following rates:

Qualification	rate
Doctorate	£3,483 to £4,063 p.a.
Masters Degree	£2,835 to £3,282 p.a.
Primary Degree	£2,431 to £2,847 p.a.

Applications, including a full curriculum vitae and the names of two referees should be sent as soon as possible to

Dr A. F. Roddy,

Department of Physics

University College, Galway
from whom further details are available. 1042(E)

RESEARCH FELLOWSHIP

Postdoctoral Fellowship in Human Cell Biology tenable for two years in the first instance with possible extension for a third year, available from January 1978 for studies on the regulation of DNA, RNA and protein synthesis and on the expression of breast specific function in primary cultures of human normal and dysplastic breast tissue. Candidates should be experienced in cell culture and in the biochemistry of growth regulation.

Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr R. Hallows (tel. 01-242 0200 ext. 307). Applications with curriculum vitae and names of two referees, should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by January 31, 1978 (Quoting ref. 33/78). 984(E)

UNIVERSITY OF SURREY

DEPARTMENT OF

BIOCHEMISTRY

M.Sc./Ph.D. IN

TOXICOLOGY

Applications are invited from graduates in medical, veterinary, biochemical or biological sciences for places on a twelve-month MSc course in Toxicology for the session 1978-79. Applicants with some relevant experience in toxicology will be favoured. After completion of the M.Sc. degree, suitably qualified students may undertake a toxicological research study leading to Ph.D. A limited number of M.R.C.-supported studentships for the M.Sc./Ph.D. are available, but these are restricted to British subjects with a good honours degree.

The course is unique in providing a multidisciplinary postgraduate training programme in Toxicology which is run by the Department of Biochemistry with the participation and collaboration of the Medical Research Council Toxicology Unit, the British Industrial Biological Research Association and the Toxicology Laboratory of Shell Research Ltd. Additional contributions from, and visits to, other major academic and industrial research organisations also take place. The aim of the course is to give graduates an understanding and appreciation of the many disciplines involved in Toxicology, with particular emphasis on the molecular mechanisms of chemically-induced toxicity, and the assessment of toxicological hazards in the manufacture and use of new chemicals, pesticides and drugs. The course provides a broad biological education and is suitable preliminary training for industrial laboratories and Government agencies concerned with the safety assessment of chemicals, and research institutes concerned with the molecular interactions of chemicals with biological systems.

The closing date for applications is February 27, 1978. Forms and any additional information may be obtained from:—

Dr K. Snell, Department of Biochemistry, University of Surrey, Guildford, Surrey GU2 5XH (Tel. Guildford 71281, extension 822). 1091(D)

UNIVERSITY COLLEGE GALWAY, IRELAND RESEARCH FELLOWSHIPS ON HEAT PUMPS

Applications, stating qualifications, age and experience, are invited from Physicists or Engineers with experience to about postdoctoral level. Closing date is January 30, 1978.

Further information may be obtained from the Secretary, Department of Physics, University College, Galway (IRELAND). 1043(E)

Commonwealth  of Australia

QUEEN ELIZABETH II FELLOWSHIPS

Physical & Biological Sciences

To commemorate the Royal Visit to Australia in 1963 the Australian Government established the Queen Elizabeth II Fellowships Scheme. Under this scheme up to ten fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proven capacity for original work. These are post-doctoral awards tenable in an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS: Queen Elizabeth II Fellows must be either Australian or United Kingdom citizens. They should have a Ph.D., or equivalent

qualification, in one of the physical or biological sciences (which are deemed to include mathematics and the scientific aspects of statistics, engineering, metallurgy, agriculture and medicine). Awards will, in general be restricted to applicants who are not more than 30 years of age on the date when applications close.

STIPEND: \$15,888 (Australian) per annum – increased to \$17,077 per annum at age of 28 years.

ALLOWANCES: are payable in respect of a Fellow's dependent spouse (\$500 p.a.) each dependent child (\$200), superannuation payments (up to 10 per cent of stipend), appropriate insurance coverage and necessary travel expenses.

APPLICATIONS: Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from the Secretary, Queen Elizabeth Fellowships Committee, Department of Science, P.O. Box 449, Woden A.C.T. 2606, Australia; the Minister (Scientific), Canberra House, 10-16 Maltravers

Street, London, WC2R 3EH U.K.; or the Consul General, Australian Consulate General, 636 Fifth Avenue, New York 20, N.Y., 10020 U.S.A. Applications for the next round of awards, which will be announced in June 1978 close at the Canberra address on 10 March 1978.

1054(E)

MENTAL HEALTH FOUNDATION RESEARCH GRANTS

The Research Committee of the Foundation exists to foster and support research in all fields bearing on mental health, mental illness and disorders of mental development.

The Committee meets twice a year to award RESEARCH GRANTS TO PROVIDE SCIENTIFIC ASSISTANCE, EXPENSES or EQUIPMENT for research workers.

For Grant application forms and further details apply in writing to:

The Honorary Secretary (N),
The Research Committee,
Mental Health Foundation,
8 Wimpole Street,
London W1M 8HY.

MENTAL HEALTH FOUNDATION FELLOWSHIPS

Applications are invited for Mental Health Foundation Fellowships from suitably qualified persons wishing to pursue Full-time Research Work bearing on problems of mental health, mental illness, or mental handicap, whether in clinical psychiatry or in one of its supporting sciences.

Both Junior and Senior Fellowships are offered in the salary ranges of Junior/Senior Lecturer, Junior/Senior Registrar, according to seniority and experience, plus superannuation. The appointments, which are also open to candidates from overseas, will be for up to three years in the first instance and in exceptional circumstances may be extended to five years. Interviews will be held in May in London and the Fellowships will be taken up between the following July 1 and March 31. Overseas candidates if short-listed, must attend for interview at their own expense.

Closing date: March 31

Application forms and further information may be obtained from the Secretary (N), Research Committee, Mental Health Foundation, 8 Wimpole Street, London W1M 8HY.

1105(E)

EUROPEAN MOLECULAR BIOLOGY ORGANISATION INTERNATIONAL WORKSHOP

on
CYANIDE METABOLISM
August 14-18, 1978

The workshop, which will be limited to 60 participants, will be held at the University of Kent at Canterbury, Great Britain. There will be sessions on plant cyanide production, cyanide production by microorganisms, cyanide utilisation, structure of cyanogenic compounds, cyanide toxicology, ecology of cyanogenesis, etc.

Particulars and application forms may be obtained from the Organising Secretary, Dr C. J. Knowles, Biological Laboratory, University of Kent, Canterbury, Great Britain. Some funds are available to enable younger scientists (aged under 30) to attend. The deadline for applications is May 31, 1978.

The Graduates

Not all of our Iodine-125 candidates pass their final exams, but those that do are exceptionally well qualified to join your laboratory.

Exam #1: ¹²⁵I Radiochemical purity —
The activity must be in the iodide form;

Exam #2: ¹²⁵I Radionuclidic purity —
The amount of ¹²⁶I must not exceed 0.05%;

Exam #3: ¹²⁵I Base strength —
Exactly measured and reported with every shipment;

Exam #4: ¹²⁵I Labeling efficiency —
Tested in a sensitive lactoperoxidase iodination.

NEZ-033 Standard package:

0.1ml of ~ 0.1M NaOH solution

NEZ-033H High Concentration:

> 350mCi/ml in ~ 0.1M NaOH solution

NEZ-033L Low pH (8-10):

High Concentration (> 350mCi/ml) in aqueous solution

Send for our new Iodine-125 products brochure.

Not for use in humans or clinical diagnosis.

Pharmacia Peristaltic Pump P-3

**A compact pump
electronically controlled for
constant liquid flows in
chromatography and
gradient formation**

You can

- obtain three different flow rates at the same time through the three individually tensioned pumping channels
- change tubes in seconds with the snap-in cassette
- forget about pulsation thanks to the large driven rollers
- rely on a constant motor speed, electronically compensated for load and temperature
- use any flow rate between 0.6 and 400 ml/h per channel with the same gear box
- reverse the flow instantly
- push for maximum flow and clear pump lines rapidly

If somebody tries to sell you one, find out what's behind it.

If it's true that imitation is the sincerest form of flattery, then we're feeling very flattered indeed! Because everyone seems to be making fume cupboards like ours these days. And why shouldn't they? They're not all that difficult to make – though the original designs did take us many years to perfect!

But unfortunately for our competitors and for their customers, too – although it's easy to copy our fume cupboards, it's absolutely impossible to match our experience.

Behind every fume cupboard we make, there's over 40 years of never ending research, not just into fume cupboard design and performance, but into complete fume extraction and air input systems, as well. Which is why we don't regard the fume cupboard as just another piece of laboratory furniture. Some manufacturers do – and they're quite happy to sell you one with no questions asked.

We're not.

We want to know what it's for, where it's going, how it's to be used ... then we can provide you with a complete back up system to ensure that your fume cupboard operates with maximum safety, efficiency and economy.

So, if you just want to buy a fume cupboard, you can get one almost anywhere. But if you want to choose a fume cupboard from the widest range in Europe and then have a complete extraction system designed around it and installed by experts who've been doing it successfully for nearly 50 years, there's only one company that can help

New liquid scintillation review

Sample preparation in liquid scintillation counting by C.T. Peng.

A recent title in our series of Review Booklets on subjects of interest to users of radioisotopes. It includes a brief account of liquid scintillation processes, and a review of the various aspects of sample preparation.

The booklet will bring the most pertinent information on sample preparation to new users and more recent developments to those already familiar with the technique.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if ' a ' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

- (i) only one reference number need be used if the reference is to several papers by identical authors.
- (ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Directed outgrowth of optic fibres regenerating <i>in vitro</i>	P. R. Johns, M. G. Yoon and B. W. Agranoff	360

Science in the EEC still a problem

If there is one thing on which all involved European scientists and administrators agree, it is that a research and development policy for the European Economic Community is proving a mighty difficult thing to bring forth. There are many reasons for this. One is that there have long been doubts that the community of nine nations should be concerned other than peripherally in basic research—institutions such as the European Science Foundation, the European Molecular Biology Laboratory and CERN draw from a wider range of nations. Another is that applied science and technology policy is difficult to devise in the absence of a broad community-wide economic policy and the sort of political union which makes British taxpayers less agitated if the R & D funds they provide lead to the establishment of new industry in, say, Italy. Finally, the policy must take note of already existing community laboratories at Geel, Petten, Ispra and Karlsruhe—the so-called Joint Research Centre—a hangover from Euratom days when there was a naive and erroneous belief that the then community members, already lavishly equipped with their own nuclear research laboratories, would have work for yet another lavishly-equipped and wide open facility.

Add to this differences in the aspirations of larger and smaller nations and the tiny dimensions of the community's R & D budget in comparison with those of individual nations (1½% of the combined non-defence R & D budget of member states), and you might reasonably wonder whether it was worth the community persisting in trying to keep a scientific programme going. In July 1977, however, the Commission of the Community had a go at bringing some new order into the science and technology programme, with a document devoted to intentions for 1977-80 and draft resolutions and decisions embodying these intentions (*Nature* 268, 96). The House of Lords Select Committee on the European Communities has been considering the evolving policy and hearing evidence from scientists with European interests. Their report is now published (Commons Paper 37; £2.60). For those who imagine that any committee of Lords could hardly get to grips with such an esoteric matter, it should be added that the committee comprised several scientists and engineers, including Lords Ashby, Hinton and Zuckerman.

It was perhaps unfortunate that the committee had completed its gathering of evidence before the Commission's report was published, for although there were some interesting presentations on the European dimension to science and a particularly spirited contribution from Professor Pierre Aigrain, it is difficult to see some of the committee's conclusions on the community document emerging very clearly from their earlier deliberations; indeed one draft decision on industrial research which the committee commends does not seem to have been the subject of any discussion whatsoever. Even so, it is possible to discern from the general drift of the evidence that the community is of most value when it is used simply to co-ordinate national research ('concerted action'), some value in financial support of domestic projects of community-wide interest ('in-

direct action') and at its most problematical when the research is done in the Joint Research Centre ('direct action'). Not least of the problems in the last case is the bureaucratic constraint imposed on the actions of the director at Ispra which gives him less freedom than a laboratory director might reasonably expect. The freedom of Sir John Kendrew at EMBL to run his own show was not lost on the committee.

What, then, to do about the JRC? The community's document recommends, somewhat bravely, a mixed diet of nuclear safety, new energy sources, environment, resources and services. The Lords' committee suggest simply a "useful role in carrying out work not done elsewhere and, for example, 'ungrateful' research"—the latter being long-term unspectacular research. This, if anything, seems a recipe for even more dissatisfaction; a huge research laboratory devoted to unwanted projects is hardly likely to find a director able to give it even nominal cohesion or to prevent it from slipping rapidly into oblivion.

It is, however, the committee's views on forecasting which leave most to be desired. Some years ago the community established a group called Europe+30 to look into whether there should be long-term forecasting capacity, together with an Office of Technology Assessment, in the EEC. The group, under Lord Kennet, made its report in 1975 (now published in edited form as *The Futures of Europe* by C.U.P.). Its recommendations included the establishment of a permanent unit of between 30 and 70 people looking at all issues of concern to the community. Lord Kennet had a tough time when he appeared before the committee, which on that day notably lacked the scientists mentioned earlier. He or his team were accused of misuse of the English language, superficiality, amateurism, exceeding their brief and so on. But after the committee had heard from Lord Kennet and before the report was written, the community made its own move on forecasting. It proposed an attenuated version of Europe+30 called FAST—a forecasting-and-assessment-in-science-and-technology programme. This, as its name implies, would be restricted to one sector and would accordingly have a much smaller staff, probably of ten.

The Lords' committee, noticeably sceptical towards Europe+30, claims that FAST will be too diluted to be of value to the community. This is not argued out at all, and indeed could conceivably have gone the other way—that work in one sector would be more concentrated and hence of more value to the community. What is suggested in place of FAST is a scientific adviser, or team, reporting direct to the President. This is difficult to take seriously, particularly coming from Britain where, for better or worse, a scientific adviser reporting direct to the Prime Minister no longer exists.

Whatever happens in Brussels, it is time now for the Council of Ministers to take firm action. As the Lords remark, the ultimate responsibility for better organisation rests with ministers, and they had best wade into this problem with some vigour. □

Forecasting future transport

J. I. Gershuny, of the Science Policy Research Unit, University of Sussex, discusses the recommendations of the Department of Transport report of the Advisory Committee on Trunk Road Assessment (HMSO, January 1978)

"We were due to have a spokesman from TRRL here tonight . . . but he's been held up in the traffic!"

OFFICIAL procedure in the UK for assessing trunk road construction schemes has, in recent years, been the subject of increasing criticism. Statisticians and transport experts have claimed that the procedures are technically faulty. Local objectors to road building schemes complain that the obscurity of the methods prevents their participation in the planning process. The Leitch Committee, which reported recently, supported the technical criticisms, but did not suggest much practical help for protesters.

Decisions to build trunk roads in the UK are based on two technical procedures. One is a forecasting exercise carried out by a group at the Transport and Road Research Laboratory (TRRL) in Buckinghamshire. The other is a computerised cost benefit analysis package called COBA, developed by the UK Department of Transport and its predecessors. Both have come under increasing criticism.

The TRRL forecasting procedure is described in the report LR650 published by the laboratory. This document makes forecasts of vehicle numbers extending into the quite distant future—the final time horizon is the year 2010. It puts forward three alternative estimates of the car population of the UK at this date—25.0, 25.9 and 26.2 million cars, or 0.43, 0.44 and 0.45 cars per head of population respectively (LR650, p15). These alternative estimates are very close together by the normal standards of social forecasting; can we really be this certain?

The reason for the small range of the alternative forecasts is to be found in the forecasting procedure adopted by the TRRL group. The predictions are based on the assumption that the pattern of growth is logistic (S-shaped) over time. A logistic growth model tends towards a given saturation level at a rate determined by some causal variable or variables—in the TRRL case, national income, motoring costs and time. So the high estimate of 26.2 million cars in 2010 involves an assumption of high national income growth and low growth in motoring costs, the low 25.0 estimate assumes low income and high costs growth, and the middle one involves medium costs and growth.

A first reason that these estimates should bunch so closely together is that the very steady historical pattern of growth of vehicle numbers in the fifteen years preceding the fore-

cast showed little fluctuation with variations in incomes and costs. So when calibrating the model, the future effect of variations of prices and incomes is similarly assumed to be small in relation to the effect of the passage of time. Even large assumed fluctuations make little difference to the forecast—because on past evidence the price and income elasticities of demand for private cars is low. Sceptics doubt that historically derived elasticities necessarily hold for the future.

A second reason for the bunching is that built into the structure of the model is a tendency for the effect of the variables on the forecast to be progressively suppressed over time as the value of the saturation asymptote is approached. The saturation level assumed in LR650 is 0.45 cars per head, and since the final predictions are so very close to this we might reasonably assume that the causal variables are contributing very little to the final result. Finally, the saturation level itself is very much a matter of speculation. In spite of sophisticated presentation, the results of the exercise come down to little more than guesses.

The cost-benefit assessment package, COBA, is rather more straight-forward, being, of course, subject to all the standard criticisms of cost-benefit analysis. The system requires that planners put money values on monuments and artifacts that have no natural economic worth, but nevertheless have considerable cultural value. Furthermore, cost-benefit analyses inevitably leave some costs completely unconsidered; COBA itself takes virtually no account of environmental damage caused by road building schemes. And even were all conceivable impacts taken into account, the effect of using a market-based system of valuation is that the preferences of the rich are given much more weight than those of the poor in the assessment.

Further COBA's assessment of future benefits is based in part on the predictions of future car numbers—giving rise to the suspicion that the TRRL vehicle forecasts may be self-fulfilling. However arbitrary the original predictions are, if, on the basis of these forecasts, new roads are built, and if, as many people suspect, the number of cars increases to fill the available road space, then the volume of traffic may well grow to the forecast level—whatever that level is! Hardly a rational way of formulating policy.

It was this sort of criticism that led to the appointment of the committee of enquiry into trunk road assessment under the chairmanship of Sir George Leitch. The committee's report contains an extremely thorough and lucid review of the assessment methods as currently practised. It examines vehicle forecasting procedures and methods of economic and environmental evaluation and compares them with practices in France, the USA and West Germany.

The Leitch report recommends that the current vehicle forecasting methods should be scrapped. To replace them the committee suggests a modelling procedure that gives much more weight to those causal factors—such as household organisation, geographical location of facilities and the availability of public transport—which actually determine people's desires to own and use cars. Such models would in particular be sensitive to the effects of public policies altering the balance of costs and convenience between public and private transport; some observers suggest that encouraging the use of public transport relative to private might in the long term have an important effect on the growth of car numbers, but the present forecasting procedure is quite insensitive to such changes in policy. This sort of conditional information about the effects on vehicle use of alternative feasible public policies would be much more useful to policymakers than the present unconditional forecasts. The report—as far as it goes—is to be welcomed. □

Killer satellites

Farooq Hussain traces the history of the Soviet and US development of killer satellites

MILITARY operations depend heavily on satellites for intelligence gathering, navigation, weather information, command, control and communication. So their vulnerability to interference or destruction is a serious and legitimate concern of military planners. Satellites are delicate devices. To make one ineffective, it is necessary only to impair the performance of its sensitive equipment: its total destruction is unnecessary. As to means, radiation directed against a satellite can cause damage at much longer ranges than the effects of blast and flying debris from an explosion in the near-vacuum of space where shock waves have little effect. Nuclear warheads would be very effective against satellites—because of their lethal radiation. But the effects of nuclear anti-satellite weapons would be indiscriminate and would more than likely result in the destruction of friendly satellites as well as enemy ones. Killer satellites exploit the poor resistance of satellite components—particularly solar cells—to intense heating and radiation damage. High energy lasers can be easily directed at satellites, so their imagined use in killer satellites is extensive. Another possibility arises from the tendency satellites have to build up high electrostatic charges due to the higher electron density around the dark side of the planet. The use of ion beams directed at target satellites can cause arcing and discharge through the instrumentation either destroying or seriously damaging it. Precision guided missiles also offer the possibility of destroying satellites either by collision or by the use of a conventional warhead detonated close to the target.

The United States and the Soviet Union have signed separate treaties in 1963 and 1967 first prohibiting testing and then deployment of nuclear weapons in space. But since 1968 the Soviet Union has been conducting tests within the general Cosmos series of satellites and these have been widely interpreted by western observers as an anti-satellite development programme. In these tests an orbiting interceptor is manoeuvred so as to make one or more close passes by a target satellite. Out of the 27 such Cosmos launches that have taken place to date only seven have ended with the explosion of the interceptor and these explosions have not always been in the general vicinity of the target satellite. The latest test in which the interceptor exploded in orbit

occurred in December 1977. Other tests have taken place which have suggested that new manoeuvring techniques have been adopted for the interceptor satellites.

American concern over this satellite programme has arisen because of the sudden resumption of testing after a lapse of four years, and the accelerated rate at which testing has been taking place. One explanation for the Soviet tests is the development of reconnaissance satellites by China. Soviet testing of the Cosmos series appears to have followed Chinese reconnaissance satellite development since 1970. In addition the orbits followed by the Cosmos series seem more appropriate to interception of Chinese satellites than American ones.

American test

The only American test of an anti-satellite system took place in 1963

The American system being developed by the Vought Corporation of Dallas, Texas

when a modified McDonnell Douglas Thor missile was fired against a missile booster in low earth orbit as the target. The Thor missile was brought within the range of the target for a simulated nuclear kill but the programme was dropped following the treaties banning nuclear weapons testing and weapons deployment in space. In a follow-on project the Vought Corporation built four infra-red homing guided missiles for use with conventional warheads. These missiles were to have been launched against satellites by a booster in a direct ascent trajectory towards the target without completing an orbit of the earth. Since the missiles were to have been armed with conventional warheads they needed a much smaller kill radius than for nuclear warheads and hence greater accuracy in guidance. But the first test launch suffered a booster failure and the second a

mechanical malfunction in deploying the payload. The programme was finally abandoned because of anticipated difficulties in getting the interceptor close enough to the target for conventional warheads to be effective.

Recent advances in the available energy, frequency range, and compactness of military lasers have prompted ideas that killer satellites may be able to carry high energy continuous wave or pulsed lasers to destroy target satellites. Ground-based lasers have been in use for a few years to interrogate reconnaissance satellites. The laser beam is used to illuminate the satellite, and the spectral pattern of the reflected laser radiation can be used to interpret various characteristics of the target. Using this technique it has been possible to determine the kind of equipment on the satellite and its sensitivity. Rumours that the Soviet use of lasers in this manner had tem-

porarily blinded an American reconnaissance satellite last year were persistent in spite of official US Department of Defense denials. However general concern within the US Department of Defense and Congress has resulted in substantial increases in the American space defence budget. \$61 million was authorised for FY 1977 with \$126 million requested for FY 1978 and an estimated \$265 million being requested for FY 1979.

In September the United States Air Force announced the award of a \$58.7 million contract to the Vought Corporation of Dallas, Texas for the development of a killer satellite. The project developed out of a competition begun in 1975 between General Dynamics/Pomona and Vought to produce an unarmed miniature homing missile designed to destroy satellites by force of impact on collision. The

missile, about twenty centimetres in diameter and thirty centimetres long, is guided either by active radar or by far-infra-red seekers. Infra-red has special advantages because satellites give distinct thermal 'fingerprints'. More than ten homing missiles are carried into orbit by a highly manoeuvrable platform whose orbit is directed so as to provide the opportunity to fire missiles at the maximum number of target satellites within a minimum number of orbits. Free-fall tests of the infra-red guidance system have demonstrated mid-air activation, target acquisition and guidance to impact with a target. Electronic counter-measures against infra-red seekers (which are passive detectors, emitting no signal of their own) are more difficult than for active radar; and it is difficult for satellites to make rapid evasive manoeuvres in orbit. A similar system involving missiles armed with conventional warheads has also been under investigation.

Interpreting Soviet tests

By comparison, Soviet tests have only obliquely suggested a preference for destruction by large explosions in the vicinity of the target satellite. Since Soviet tests have never resulted in the physical destruction of a target, the explosion of the interceptor could be explained as a test of the vulnerability of the target to attack—rather than demonstrating the potential of the interceptor to destroy target satellites. The difficulty in interpreting properly the explosions in the Cosmos series also lends support to the idea that Soviet killer satellites may soon carry laser or ion-beam weapons. In any case the Soviet and American hunter-killer satellite developments should not be directly compared because each Super Power has very different approaches to the development of major weapon systems.

Presently US space defence research is concentrated upon problems of hardening satellites against attack and increasing the resistance of communication, command, and control transmissions to jamming. These battlefield transmissions now rely almost

completely on satellites. The third generation of American military communications satellites now being developed employ a technique of using multiple directional beams for transmission, and of shifting frequencies in the ultra and super high frequency bands (7 to 8 GHz) to avoid the effects of jamming. Satellite antennae are being developed that use electronic counter-measures to eliminate the effect of a directional jamming beam fixed on the satellite. Solar cells are being designed and built to withstand the effects of intense heating and radiation, by using filter coatings which do not absorb energy at typical laser wavelengths, and by using construction techniques with materials with high resistance to heat and radiation damage. The vulnerability of solar cells has led to an increased interest in nuclear power sources for satellites which until now have always

The Soviet system can only knock out one satellite at a time making it ineffective against the US global positioning array of 36 satellites

had the disadvantage of being much heavier and considerably more costly to operate. Three designs are currently under consideration all of which use P^{238} isotopes as the power source. With the considerable improvements in performance that are being achieved for satellites military dependence on them can be expected to increase throughout the 1970s and early 1980s. During the first half of the 1970s military missions accounted for about half of the American satellite launches and both the number of military satellites and their relative size and payload will increase further as the NASA Space Shuttle

begins operation.

The development of killer satellites is unlikely to provide any significant strategic advantage for either Super Power and the race to develop them is likely to be very costly. A surprise attack is hard to achieve with killer satellites because the preliminary manoeuvres are easily detected by other satellites. It is also possible to place in distant orbits satellites which are ready to replace ones destroyed by an attack. These so-called 'dark' satellites have characteristics such as very small radar cross-sections and low reflectivity which make them very difficult to detect and track. Because of their distant orbits they are relatively safe from attack in the first instance. The real advantage of destroying military satellites in a strategic nuclear conflict would appear only if one side destroyed a significant number of the opponent's satellites while retaining its own. A rapid destruction of all satellites would yield no advantage to either side.

It is perhaps to avoid a costly arms race that both the Soviet Union and the United States are anxious to reach an agreement limiting the development of killer satellites. The United States was reported to have requested Soviet consideration of such an agreement last March. The Soviet response was favourable and the United States National Security Council are presently considering a formal policy based on reports by various departmental agencies on the implications and verification problems of a hunter-killer satellite limitation or ban. The intention is to provide for an agreement separate to SALT and talks on a possible agreement over limiting killer satellite development may begin this Spring. Meanwhile US Defense Department officials are concerned that present programmes should not be effected by the agreement and it is unlikely that the incentive given to US space defence research by the recent Soviet testing of the Cosmos satellites will be abated by a limitation—unless the form of the agreement is radically different to those which have been made in other areas of strategic arms control. □

1979 looks like a good year for US science

CLIMATOLOGY, reproductive and developmental biology, and military-related basic research are three areas of science likely to receive a major boost from President Carter's Budget for the fiscal year 1979, which was submitted to Congress on Monday.

Other areas to benefit from a budget that proposes an overall increase of 10.9%—about 5% above expected in-

flation levels—for basic science include solar studies, which is given the green light for two major projects, and earthquake research. Potential casualties include one of the five planned space shuttles, and the Clinch River liquid metal fast breeder reactor demonstration project. The proposed termination of the Clinch River project would save about \$150 million, and would

result in virtually no increase in the energy research and development budget overall.

In general, the budget carries an optimistic message for basic science, in line with the results of a broad-ranging survey of the nation's research activities carried out at the President's request by the Office of Science and Technology Policy (OSTP). The projected

increase in spending on basic research is precisely the level recommended by the President's Science Adviser, Dr Frank Press, who claims "100% support" from the Office of Management and Budget.

But if previous budgets could be described as Keynesian, this one returns to a more classical, monetarist mould. Emphasis in funding is shifted away from development projects (for example in solar heating technology) which are felt to be the responsibility of the private sector and its market forces, back to more basic "long term" considerations.

Thus within an overall increase in support for research and development of 6.1%, to a total of \$27,900 million, the main increase will take place in basic science, from \$3,288 million in 1978 to \$3,647 million in 1979. In contrast the budget for applied research will increase by only 7.4% from \$6,248 million to \$6,711 million, and for development by an even lower rate of 4.6%, from \$16,753 to \$17,532 million.

A major beneficiary of the increased funding for basic research will be universities and colleges, many of whose problems—such as the obsolescence of equipment and the lack of opportunities for young scientists—were brought to the President's attention by the OSTP survey. Total R & D support for colleges is therefore suggested to rise from \$3,300 million in 1978 to \$3,561 million in 1979, an overall increase of 7.9%, with particularly large increases in funds for agricultural (10.7%), energy (11.7%), and military research. (In the light of the benefits which these increases are expected to bring, the NSF's proposed basic research stability grants, whose \$4.5 million was "impounded" by the President from the 1978 budget a few months ago, will be permanently dropped.)

One area to receive a major boost is climate research. A broad initiative in this area, involving eight agencies and a 39% increase in funding to \$104 million, will be coordinated by the National Oceanic and Atmospheric Administration of the Department of Commerce.

Three important aspects of the proposed 1979 budget will be: the development of satellite sensors for ozone and earth radiation monitoring—a major field study of the equatorial Pacific—and basic research on carbon dioxide levels in the atmosphere and oceans.

Two new programmes are included in the budget of the National Aeronautics and Space Administration (NASA). The first of these is the Solar Polar Mission, a joint project with the European Space Agency to send two space craft, launched from the Space Shuttle in 1983, past Jupiter, in an orbit that will permit the first study of

the polar regions of the sun. And the second project is the Solar Mesospheric Explorer, which will permit study of the effects of solar radiation on the earth's ozone layer.

At the Department of Health, Education and Welfare, whose basic research budget is proposed to be increased by 14.9% to \$992 million, areas scheduled for increased support include reproduction and family planning, developmental biology, and child development, as well as the potential environmental hazards to human health.

There are bright prospects, too, for military-related basic research. Spending by the Department of Defense is proposed to increase by 14%, almost as much as for health research, reflecting the view of Defense Secretary Dr Harold Brown that this area has been underfunded in recent years.

One result of this will, according to Dr Press, be the re-establishment of connections between the military establishment and the university research community which, he says, "have been allowed to lapse in recent years" and the R & D budget of the Department of Energy includes provision for work on the controversial neutron bomb.

The future for basic research—at least in most areas—therefore looks better than it has for several years past. But the *leit-motif* remains that of the ultimate pay-off. Dr Press, pointing out that the applications of basic science may take 10 or 20 years to come through, characterises this as an area in which industry tends as a consequence to "underinvest", thus justifying increased federal expenditure. And Dr Robert Frosch, administrator of NASA, ended his statement on the Agency's budget with the words that it would "give the American taxpayer the return on his investment he expects and deserves".

This approach is also reflected in the budget of the NSF. One area due for significant expansion, for example, is the integrated basic research programme of the new Applied Science and Research Application Directorate.

This is scheduled for an increase from \$1.9 to \$7.0 million, and will be concerned with "identifying basic research relevant to significant national problems", jointly with the basic research directorate of NSF.

One area to have suffered from this cost-conscious approach is high energy physics, whose budget is planned to expand by only 6.7%. The budget allows substantial sums for the construction of the intersecting storage accelerator (Isabelle) at Brookhaven, and for a new high-intensity beam facility at the Lawrence Berkeley Laboratory.

At Fermilab in Illinois, however, although the energy saver/doubler project is being formally moved from the R & D to the construction phase, only \$10 million of the proposed authorisation of \$38.9 million for construction is scheduled to be spent in 1979—and this will be partially met by reducing the \$86.1 million authorised for running costs in 1978 and \$81.8 million authorised in 1979.

But if the cost/benefit consciousness that runs through the proposed budget has resulted in decisions that are unwelcome in some quarters, it is likely to increase the chances of the budget proposals being looked upon favourably by Congress.

Last year, the substantial increases for research and development requested by President Ford in his outgoing budget were received sceptically. Although making a considerable, and almost traditional, increase in the NIH budget, Congress reduced the request for the NSF, for example, from \$885 million—a figure which NSF Director Dr Richard Atkinson admits "we were not able to defend"—to \$863 million.

This year the OSTP has done the President's homework. And there will be both substantial evidence, and the carefully-considered support of departmental and agency heads, to back up demands in the face of Congressional cross-examination. So the signs are that 1979 will be a good year for scientists.

David Dickson

Anti-relativist draws others into the whirlpool

Stefan Marinov

*O father Galileo, cunning one and wise,
Thy trial persisteth still even from age to age;
Moralist and philosopher try thee, the fool eke tries,
And everyone who counts himself a learned sage.*

*So wast thou then a coward, valourless, without honour,
Thyself knowing the truth, to spit on truth, deride,
Saving thy mortal frame, to fraud to sing "hosanna",
Before all men to trample thine honour and thy pride.*

*Holy lord of the spirit, my teacher wise and dear,
Is the common herd worth our torments and our blood.
Shout yourself hoarse—no sound will reach its blunted ears;
Throw your heart at its feet—onward it still doth plod.*

*So, doctors, I bow and swear: "There is no absolute space!
All I affirmed is lunacy—bring on your drugs apace!"*

RESTRICTIONS on scientific correspondence in the Soviet Union and its satellites have, over recent years, become familiar—the classic study of the problem being *The Medvedev Papers*. One of the most curious by-products of the system is the recent appearance, in Belgium, of an anti-relativistic tract with the lofty title *Eppur si Muove* and a preface signed by no less a person than A. D. Sakharov—presumably the dissident academician of that name. In fact, as the author of the book, Stefan Marinov, himself admits, Sakharov never wrote such a preface; Marinov claims, however, that Sakharov gave him permission to append his name to a preface written by Marinov on his behalf.

Although this may appear at first glance somewhat a trivial matter—that of a 'fringe scientist' trying to gain the backing of an eminent member of the orthodox community—the appearance of the preface could have considerable implications for Academician Sakharov. The various campaigns launched against him within the Soviet Union regularly imply that he has 'abandoned' or 'betrayed' science for 'so-called dissidence', and his apparent endorsement of a scientific theory which he himself does not hold, simply because its author was himself in trouble with the authorities in his own country, could add valuable fuel to this debate. The history of this curious preface is therefore worth looking into.

Stefan Marinov first made his appearance in the western media in the autumn of 1976, when large advertisements began to appear for a conference on 'Space and Time Absoluteness' the following May, on his initiative. A certain 'A. D. Sakharov' of Moscow was listed, variously, as Chairman or Patron of the conference. This surprising announcement led to considerable speculation, and a general consensus of opinion that it could not be Academician Sakharov who was meant. Even the difference in spelling

was cited to support this idea, by those who did not realise that the Russian name САХАРОВ would, in certain transliteration systems, be rendered as 'Sacharov'. In fact at the time of the announcement, Marinov and his western supporters were still trying to contact Academician Sakharov by telephone, to ask for his consent, and were approaching anyone (the present author included) whom they felt might be able to make such a contact.

Marinov's next attempt to contact Sakharov came the following spring. His *magnum opus*, refuting the theory of relativity and all associated physics, was ready for publication, and he wished Sakharov to provide a preface. Having still failed to contact Sakharov over the Varna Conference, Marinov wrote the preface himself, distributed copies to possible contacts with the request that they forward them to Sakharov, and added a covering letter which, in the manner of a student applying for an *exeat*, said that unless he heard to the contrary, he would assume that he had Sakharov's permission to proceed. In one version of the covering letter, he added a brief self-portrait. "As far as I know, I am the unique 'dissident' in my country (once in a prison, twice in a loony bin). I descend from an old family of intellectual communists, and I am a Marxist (I have even written a book on mathematical political economy—in Russian—and I have a translation in Serbo-Croatian). My opinions are most close to those of Roy Medvedev."

Marinov was soon to be back in the mental hospital for a third time. At the end of April 1977, telegrams signed 'Marinov' were sent to journalists and others who had any connection with the Varna conference, cancelling it on the grounds that an earthquake was expected. The immediate assumption, that Marinov had taken this means of cancelling an event which had no supporters, proved false. Marinov had been removed to hospital by the authorities,

who had then notified in his name all those on his address list. News of this reached the West in May, but journalists were earnestly requested by his friends not to publish, since this would endanger his life. In all events, once the critical dates of the planned conference were over, Marinov was released, and in late summer he was allowed to emigrate. He settled in Belgium.

In October, 1977, the news-magazine *Pourquoi Pas?* carried a massive article on Marinov, 'The Scientist who came in from the cold', with a reprint of the 'Sakharov' preface. This, allowing for translation and editorial omission, was identical with Marinov's own draft. Although it seemed highly unlikely that Sakharov would have lent his name, I decided to seek confirmation on this point. It is virtually impossible to get a letter through to Sakharov, and direct telephone contact is likewise a random matter with minute probability of success. Nevertheless, the message reached Sakharov by two channels, and two answers were received. One, via a physicist, ran 'Academician Sakharov knows of the book, but did not wish to be associated with it, as he does not agree with the theory!' The other, less formal message, was transmitted as 'Andrei Dmitrievich says: "The man's a nut-case (*psikh*), but I wouldn't want to condemn anyone to a mental hospital!"'

At the end of November, Marinov turned up, uninvited, at the Science Session of the Venice Biennale. Asked about the preface, he maintained that a 'courier', described as 'an eminent physicist' and a 'young girl', had taken the book to Sakharov who received the courier, expressed sympathy for Marinov's plight, and agreed to 'think about' the matter of the preface. Sakharov is well known for his kindness and compassionate interest in all those in trouble; and he probably meant simply to give an expression of personal sympathy coupled with a polite refusal

to involve himself with Marinov's theories. Unfortunately, Marinov construed this as consent to have his signature added to the preface. Although a number of people entreated Marinov to withdraw it, he refused, saying that as it had appeared in *Pourquoi Pas?* it was now too late to do so. Moreover, he needed Sakharov's name to sell the book; unless he could sell 5,000 copies at \$20 each he could not get the money he needed to carry out the experiments described in it. (One presumes he meant 'replicate'.) A long and hysterical telex was dis-

patched to Sakharov c/o the Soviet Academy, and copies circulated among the Biennale journalists. Sakharov at that time was not even in Moscow; he and his wife were staging a sit-in in a Siberian labour camp where her nephew Edvard Kuznetsov, the dissident writer, had been refused his regular visit from the Sakharovs. At the time of writing, Marinov is still trying to get a message through to Sakharov.

Marinov's experiences in defence of his theories have undoubtedly made him only the more adamant in maintaining them. His poems imply that

his incarceration in the mental hospital was on account of his theories (see sonnet opposite). Clearly he is willing to take any means to promulgate them, even resorting to 'short cuts' when no answer is forthcoming. This is almost certainly not the first such occurrence in the long history of East European censorship—a number of very curious documents have reached the West from time to time. The whole episode is yet another illustration of the curious situations which can arise when governments restrict the freedom of scientific contact and correspondence.

Vera Rich

Polishing a tarnished image

LAST Wednesday the centre of Washington was brought to a standstill by a demonstration of angry farmers demanding "100% parity"—a price for their products that would give them the buying power of 65 years ago, when agricultural prices were at their peak. That same afternoon, a group of congressional employees was given a seminar on "government's role in scientific research" by a group of distinguished biomedical scientists, including three Nobel laureates—Arthur Kornberg, George Palade and James D. Watson—and the heads of some of America's leading biomedical research institutions and medical schools.

The style was different from that of the farmers, but the demand was very similar: a return to the levels of funding that basic research in the biological and medical sciences enjoyed in the relatively halcyon days of the late 1960s.

The case that the scientists presented during a well-organised two-day visit to Washington—which included private meetings with congressmen and members of the administration, as well as public hearings before the appropriations committees of both the Senate and the House—was straightforward. Basic research, they claimed, is grossly underfunded in comparison with applied research—it is in a chronic state of instability and lacks the means of training a new generation of scientists.

"We are here to draw to the attention of our legislators the importance of basic biological research in the solution of major elements of our nation's health care problems," Dr Mahlon Hoagland, President of the Worcester Foundation for Experimental Biology, and a major organiser of the Washington visit, told Senator Thomas Eagleton's appropriations subcommittee on the budget of the Department of Health, Education and Welfare.

On the surface, the argument was

about money; the report in the *New York Times* carried the not unfamiliar headline "Scientists plunge into lobbying for more medical research aid". And the scientists presented a carefully-quantified list of grievances.

For an example they claimed that there has been an 18% drop in the total amount of federal funds spent on basic research since 1967, and a reduction of 17% in support for scientist-initiated grants awarded by the National Institutes of Health (NIH) between 1967 and 1975.

Between 1967 and 1977 there was a decrease in the proportion of grants funded to grant applications submitted from 53% to 33%, they told the subcommittee. And the scientists also pointed out that there has been a decrease in funds for training young scientists from 18% of the NIH's extramural budget in 1967 to 6.8% in 1976.

The demands, too, were specific. The group said that it wanted the NIH to be provided with an across-the-board increase in funding of 10% in the fiscal year 1979 to compensate for the effects of inflation, and a return to 1967 levels in both scientist-initiated grants for basic research (then 61% of the NIH external budget) and the biomedical research support grants system (then 7%).

In addition, they requested an extra \$100 million a year for five years (an increase of almost 50% over the current budget) to be added to the budget of the National Institutes of General Medical Science, the NIH's basic research institute through which many biomedical research activities in universities and medical schools are funded.

Yet the visit to Washington was not only—or indeed primarily—about money. Indeed on purely statistical grounds, the case that the scientists presented lay open to criticism. It was pointed out, for example, that by taking the 1967 figure as a bench-mark, a

year in which research funding is generally reckoned to have reached the peak of the 1960s expansion, figures for subsequent years appear particularly—and perhaps artificially—bad. And figures presented purely as percentages obscure the almost 300% increase in total funding for NIH.

Furthermore both NIH and President Carter's Office of Science and Technology Policy have shown themselves to be aware of the current problems facing the basic research community. After what everyone agrees was a bleak period between 1967 and 1972, funds for basic research have been picking up, and will continue to do so if Congress accepts the suggested increases in President Carter's budget proposals presented this week.

But behind the dispute over financial resources lies a deeper issue of concern to the scientific community, the public image of science, and in particular of basic science on which Congress's willingness to provide additional funds ultimately stands.

In recent years, just as the debate over the implications of the Rothschild Report in Britain have reflected growing demands for the "relevance" of medical science, so similar tendencies in the US have given rise to what has been called the "disease of the month" mentality with a philosophy that medical science should be primarily directed towards curing, rather than understanding a disease.

In this climate, as funds have come pouring in for research into disease-related programmes such as cancer and heart disease, resulting in the total NIH budget increasing from about \$1,000 million to over \$2,500 million in seven years, so basic research has—in relative terms—lagged behind, and the process of scientific discovery has, it is claimed, been both distorted and delayed.

In the eyes of many basic scientists the villain of the piece is the so-called "war against cancer" launched in 1971

with President Nixon's much-heralded National Cancer Act, and responsible for an increase in cancer research funding from \$180 million in 1970 to almost \$900 million in 1978.

No one is claiming that the money has been entirely wasted. Much good science has been carried out under the cancer programme, and despite occasional widely-publicised lapses, few are prepared publicly to identify specific projects which they feel should not have been funded.

But various factors have led to a cooling off in Congress' initial enthusiasm for a massively-financed cancer research programme, and to increasing demands for a visible pay-off from its investment. These factors include data showing that, in spite of all the research and clinical advances, deaths from cancer continue to increase, and the growing evidence that many cancers are due to environmental causes, accessible to preventive rather than curative techniques.

Congress' frustration at the lack of tangible results reinforces the view of those scientists who criticised the whole "target-oriented approach", to biomedical research funding from the beginning. The fear, however, is that a failure of strategy could result in a general disillusionment with the whole research enterprise, affecting both its basic and applied aspects.

Dr Arthur Kornberg, for example, professor of biochemistry at Stanford University, claims that it is very rare for a crash programme of biomedical research to succeed in its objective, but warns that failure also carries its price. "Progress in medicine rests on fundamental advances. You harm people by trying to do things prematurely—you destroy your credibility, and the whole of science suffers. We have seen this happen in recent years, and people are discouraged from entering a field which has come to be regarded as bad science."

Dr Kornberg criticises the extent to which research workers are increasingly required to keep their eyes on a fixed target. "At present we have to boot-leg under various guises if we want to carry out fundamental research. This has both the spirit and the content of scientific investigation."

The task therefore facing the biomedical community, confronted by an apparent failure to come up with the goods that congress—many feel unjustly—has demanded, is how to make it respectable to be seen giving money to basic research in the biological and medical sciences. Criticism of the cancer programme, for example, will be to no purpose if the net result is an overall reduction in NIH research funds, rather than a redirection of

Dr Arthur Kornberg

funds towards basic research.

Furthermore Congress has no direct control over the way that the directors of the various NIH institutes distribute the funds allocated to them. A suggestion that each institute be required to spend at least 30% of its budget on basic research would be "a mistake" according to Dr Donald Frederickson, Director of NIH, who points out that most institutes do this already.

The best that scientists can hope for is some recommendation from Congress that it would like to see the various institutes upgrade basic research, a suggestion to be checked later against actual performance. "I feel that some of the institutes have tended to overemphasise target research at the expense of basic research because that was what Congress wanted. But Congress might now take the opportunity to communicate its belief in the importance of basic research," Dr Seymour Kety, Professor of Psychiatry at Harvard University and a past scientific director of the National Institute for Mental Health told the Senate Appropriations Subcommittee.

So far, the response of several key Congressmen has been relatively favourable. Sensing a growing disillusionment with the target-oriented approach to research funding, they are prepared to back the case that the long-term solutions lie in supporting basic research.

Mr Eagleton, for example, told the scientists that his subcommittee had "become aware of the pitfalls brought on by the proliferations of targeted research programmes." And Representative Paul D. Rogers, Chairman of the House Subcommittee on Health and the Environment, has promised to introduce a research training grants bill that would provide an extra \$220 million in 1979.

But the case is far from conceded. Cancer research still has powerful supporters who, while accepting that it is

the quality rather than the quantity of research that matters, claim that this means more rather than less money. And there remains the widespread feeling in many quarters—frequently voiced, for example, by Senator Edward Kennedy—that medical scientists should be required to produce results of visible social usefulness to justify the large investment of public funds that they receive.

Thus in spite of a significant increase in federal support for basic research in the proposed budget for 1979, basic biomedical science is unlikely to achieve its "100% parity" with the boom years of the late 1960s. At least not in the near future. The most that scientists can hope for is that they can encourage the pendulum to swing a little faster in their direction.

David Dickson

Lederberg named President of Rockefeller University

Professor Joshua Lederberg, Chairman of the Department of Genetics at the Stanford University School of Medicine, and Nobel prize winner in 1958 for his work on the organisation of genetic material in bacteria, has been elected President of the Rockefeller University in New York. Professor Lederberg will take up his appointment from 1 July and succeed Dr Frederick Seitz.

UK science budget announced for 1978/9

Spending on science through the UK research councils will be up by more than 2% in real terms in 1978/9, claim the Advisory Board for the Research Councils (ABRC) following agreement between the Board and the Secretary of State for Education and Science on expenditure levels. The Science Budget, which funds the research councils, Natural History Museum and Royal Society, is £256 million at 1977 prices; the Science Research Council get £139 million of it. The figures include two increases recently authorised, one for a recurrent £4 million following a slight easing of the economic situation, the second for a once-off £4.5 million to stimulate the construction industry.

The distribution of the budget still reflects ABRC's intention gradually to redeploy resources away from big science but there is now sufficient leeway with the extra money for one person at SRC headquarters to describe the mood there as "reasonable satisfaction, even modified rapture".

International Ultraviolet Explorer to be launched this week

DURING the course of evolution some animals have developed eyes on stalks as a rather bizarre adaptation to their environment. Astronomers could well do the same to escape the disturbing effects of the earth's atmosphere but evolution is a slow process and, luckily, there are more acceptable solutions. For many years now, astronomers working at wavelengths that are absorbed by the atmosphere have been sending probes into space, but the available techniques have not been entirely satisfactory. Rockets and balloons provide only fleeting glimpses and orbiting satellites not continually in communication with the ground must be automated to collect data blindly for later transmission. A solution is required which enables the astronomer continuously to control and monitor the performance of a telescope that remains above the atmosphere for long periods of time.

That solution is provided for the ultraviolet (UV) wavelength region by the International Ultraviolet Explorer (IUE) satellite scheduled for launch into geosynchronous orbit on 26 January. The satellite will be continuously visible from a control station on the ground and can be used just as if it were a ground-based UV telescope not suffering from the effects of the atmosphere.

In the ultraviolet region those effects are disastrous. The earth's atmosphere becomes increasingly opaque at wavelengths below 4,000 Å and is effectively 'black' beyond 3,000 Å. Balloons can observe over most of the mid-ultraviolet range from 3,000 Å to 2,000 Å by ascending above the bulk of the ozone layer to heights of 40 km, but for the far ultraviolet below 2,000 Å it is necessary to go much higher. The planned orbit of IUE varies from 25,000 km to 46,000 km altitude.

There are sound reasons for wanting information at ultraviolet wavelengths. The sun is brighter at visible wavelengths than in the far ultraviolet but this is not true for many other stars. As the temperature of a source

increases, the emitted radiation appears at shorter wavelengths and at 20,000 K, a typical surface temperature of a newly-formed star, almost all of the light is at wavelengths that cannot penetrate the earth's atmosphere.

The cooler regions between the stars are also important at UV wavelengths. Interstellar gas contains about 10% of the material in our galaxy and can be detected only by the characteristic absorption lines it imposes on the spectra of objects observed through it. The gas constituents are in their lowest energy state because of the low densities and temperatures in space and so it is necessary to observe at wavelengths where the atoms and molecules in their ground states can absorb light.

The common elements in interstellar gas are hydrogen, helium, oxygen, carbon, nitrogen and silicon. They all have their strongest absorption lines below 3,000 Å, with only the less abundant sodium and calcium appearing in the visible region. Therefore the major constituents of interstellar gas clouds can only be observed by measurements in the UV. If the gas clouds are moving, then the absorption lines will be Doppler shifted in wavelength and high resolution measurements of the spectra allow their velocity to be calculated.

Curiously, UV emission from some of the stranger objects in the sky has been studied from the ground. Many of the immensely distant quasars are receding so fast that their UV light is Doppler shifted into the visible region; they are said to have large redshifts. These cannot be compared directly with low redshift quasars whose UV emission is shifted less and still remains in the band absorbed by the atmosphere. Direct comparison is essential to find out if quasars are at cosmological distances, and the Lyman alpha line is crucial as it may provide a measure of the intrinsic brightness of quasars. So far, quasars have been disappointing cosmological objects simply because they could not be easily observed in the ultraviolet. But a recent UV observation of a low redshift quasar has imposed important constraints on cosmological models. Those measurements were made from a rocket flight and lasted only four minutes—IUE can observe for 24 hours a day.

The present knowledge of the appearance of the universe in the UV comes from balloon and rocket flights and from experiments on board the American Orbiting Astronomical Observatory satellites OAO-2 and OAO-3 (renamed Copernicus) the Dutch ANS satellite and the European TD-1 satellite. IUE is dedicated solely

to UV observations and promises an enormous improvement on the earlier, largely survey, experiments. The IUE project is itself a forerunner for the Space Telescope planned to be launched from the Space Shuttle in 1983.

There are two broad aims of IUE and these impose conflicting requirements on the instrumentation. The measurement of chemical abundances, and the study of gas motions, require a detailed study of line profiles with very high spectral resolution. But IUE should be able to detect faint sources making necessary good light collection efficiency rather than resolving power. The ability to observe for long periods also means that variable phenomena can be observed.

To satisfy these requirements, IUE carries a 1.3 m long, 45-cm diameter aperture, Cassegrain telescope which will be used exclusively for spectroscopy. No direct imaging will be made in the UV although a visible-light picture will be used for target identification. Light from the telescope is passed through two spectrographs, each containing a high dispersion echelle grating in series with a low dispersion grating; two spectrographs are needed to achieve resolutions of between 0.1 Å and 0.2 Å over the full wavelength range of 1,150 Å to 3,200 Å. For the low resolution mode, the echelle is simply bypassed, producing a spectrograph that can be used to record stars as faint as 14th magnitude with a 6 Å spectral resolution.

IUE is a joint venture between the US National Aeronautics and Space Administration (NASA), the European Space Agency (ESA), and the UK Science Research Council (SRC). The major contributor is NASA. ESA is providing the solar panels and one of the two ground stations and the SRC is supplying the UV sensitive television cameras used for spectra detectors. The observing time on IUE will be shared on a daily basis with 16 hours going to NASA, and 4 hours each to ESA and the SRC who have agreed to take 8 hour periods on alternate days.

As the telescope is in geosynchronous orbit it will be in continuous contact with the NASA ground station at the Goddard Space Flight Center and will be in view at least 10 hours a day from the ESA ground station at Villafranca near Madrid. This arrangement allows real-time operation of the telescope and reduces the training time necessary for observers. As a result, the telescope can be opened up for international use and guest observers are encouraged to use IUE in a similar fashion to ground based telescopes.

Conserving uranium

SIR,—We read with interest the recent article by John Davies on this topic (1 December, page 376). However, it does contain a number of scientific errors and misleading statements which we believe it is our duty to point out.

He is incorrect in stating that the difference between the $^{238}\text{U} \rightarrow ^{239}\text{Pu}$ and the $^{232}\text{Th} \rightarrow ^{233}\text{U}$ reactions is that the first needs fast neutrons while the second can use slow ones. In fact the cross-sections for the two reactions are almost identical at all energies and therefore they have very similar breeding characteristics. The reaction $^{238}\text{U} \rightarrow ^{239}\text{Pu}$ occurs to a very considerable extent in thermal reactors. In fact about one third of the energy output of a thermal reactor arises from the ^{239}Pu produced within it and then burned *in situ*. Thus in the UK we already get between 4 and 5% of our electricity from the fission of plutonium.

The control of both thermal and fast reactors is based on the delayed neutron contribution and this is on a time scale of seconds rather than micro-seconds. The only mechanisms for a sudden increase in reactivity are loss of coolant or fuel movement, neither of which could occur faster than the control rods could move.

Turning to the $^{233}\text{U}/^{232}\text{Th}$ fuel cycle we would first challenge the statement that ^{233}U is automatically safeguarded against illegal diversion by the intense γ -rays coming from the simultaneously produced ^{232}U . This isotope does not emit γ -rays. It decays with a 70 year half-life by α -emission to ^{228}Th which does emit the γ -rays to which Dr Davies refers. Thus only after a considerable period does the γ -activity build up to a sufficient level to afford intrinsic protection.

With regard to the waste disposal problem the thorium cycle may give rise to fewer problems from the production of long lived higher activities but on the other hand much more Pu^{238} and ^{234}U is produced. The latter isotope decays to the very hazardous ^{226}Ra .

Accelerators are replacing reactors for some forms of neutron research because they can produce neutrons in short pulses and can give higher peak fluxes than a reactor. However, the mean flux from such systems up to present is lower by orders of magnitude than in research reactors.

The use of accelerators for breeding significant quantities of fuel demands machines giving outputs two or three orders of magnitude greater than the most powerful machines built so far. The breeder target is nothing less than a very major reactor in its own right. Studies of such a system at Brookhaven suggest a cost/gm of ^{239}Pu three to five times greater than that of equivalent enriched ^{235}U . The hazards of such a system could certainly not be less than that of a major reactor system.

We do not wish to give the impression that we are in any way antagonistic to the thorium cycle or to accelerator breeding. We wish merely to warn against the temptation of assuming, like the grass being greener on the other side of the fence, that problems of an alternative technology are necessarily less than those of a technology upon which one has embarked.

Yours faithfully,
A. T. G. FERGUSON

Transposed sentence

SIR,—It has been brought to the attention of the editors of volume 23 of *Biographical Memoirs of Fellows of the Royal Society* that certain sentences in the memoir on Professor C. H. Waddington may be read as derogatory of the work of Dr Ruth Clayton and her colleagues. This was in no way the intention of the author, but arose from an unfortunate transposition of sentences in an early draft. The author therefore wishes to amend the last six lines of page 583 to read:

"... work that Waddington had originally envisaged. A notable exception which fitted into Waddington's original concept was the work on the development of the avian lens in the group led by Mrs Ruth Clayton. The laboratory became well known for the DNA-RNA investigations which earned a world reputation for at least two of the leading workers."

We must unreservedly withdraw all inferences to the effect that Mrs Clayton's work and that of her group is anything other than of the highest class and of a deserved worldwide reputation and we whole-heartedly apologise to Mrs Clayton for the embarrassment caused to her and her

group by the unfortunate misplacing of the sentences in the article.

Yours faithfully

R. W. J. KEAY

Anti-Müllerian hormone

SIR,—In a recent issue of *Nature* the authors D. Tran, N. Meusy-Dessolle and N. Josso report on a testicular factor distinct from testosterone which mediates regression of Müllerian ducts in male fetuses (*Nature* 269, 411–412; 1977). Apart from the heading of their article which read "Anti-Müllerian hormone, etc." (and which caused underlining and exclamation marks by some of my merry colleagues) I do not consider it appropriate to use laboratory-born artificial words such as 'testicular anti-Müllerian activity', 'Müllerian regression' and others in a scientific communication. I wonder how this obvious jargon escaped your referee's attention*. Besides there is no 'Müllerian regression' but a regression of the outline, the diameter or so of the Müllerian duct; likewise there is neither a 'testicular anti-Müllerian activity' nor an 'anti-Müllerian hormone'. I am sure that Johannes Peter Müller (1800–1858) would agree.

Yours faithfully,

GERHARD H. MÜLLER

Universität des Saarlandes
Saarbrücken, West Germany

*It didn't, but the authors claimed that since the name had been used in all their recent publications, a change now would cause confusion.—ED.

Essential relativity

SIR,—In connection with Paul Davies' kind review of the second edition of my book *Essential Relativity* (*Nature* 22 September 1977) I wonder if you would allow me to correct one slight error. The coordinates of accelerated observers in Minkowski space, which have recently been used in the study of black holes, are elaborated on, albeit in a later section on Kruskal space. Indeed, this was one of the more significant additions to the second edition.

Yours faithfully,

WOLFGANG RINDLER

The end of the expanding Earth hypothesis?

from Peter J. Smith

ON the face of it, this is a bad day for the handful of people who support the idea of an expanding Earth, a good day for the few who oppose it, and certainly no less than an interesting day for the vast majority of Earth scientists who have been content merely to observe the progress of the expansion debate for anything up to 20 years. For on page 316 of this issue of *Nature*, McElhinny *et al.* offer the most convincing proof yet that, despite some obvious attractions, Earth expansion is nothing more nor less than a scientific blind alley. Specifically, they use the best available palaeomagnetic data to show that over the past 400 Myr the Earth's radius cannot have increased by more than 0.8%, a figure sufficiently small to exclude the very low rate of expansion (0.6 mm yr^{-1}) proposed by Wesson (*Q. Jl R. Astr. Soc.* **14**, 9; 1973) as well as the much higher rates favoured by, among others, Carey (in *Continental Drift—A Symposium*, University of Tasmania, 1958).

So that is the end of the Earth expansion hypothesis. Or is it? Before passing the death sentence it is perhaps worth making two points which may be interpreted as reasonable caution or unreasonable scepticism, depending upon one's point of view. First, history has shown that where the Earth sciences are concerned it is often dangerous to express absolute certainty. The continental drift saga alone is sufficient indication that even the most solid of foundations may crumble, especially if they are given a kick by a passing stranger. In the case of continental drift the stranger was a meteorologist, but for Earth expansion it could well be the first physicist or astronomer to delineate the historical variations, if any, in the gravitational constant. Earth scientists have been conscious of the possibility of Earth expansion ever since Dirac (*Proc. R. Soc. A* **165**, 199; 1938) suggested that

the gravitational constant may be slowly decreasing; but although convincing proof of such a decrease has never yet been produced there is still an outside chance that it will be. In that case, of course, expansion of the Earth would have to be accepted; and however hard it may be for them, Earth scientists would have no option but to re-examine their supposedly fool-proof analyses.

But if that is a possible problem for the future, there is also the more immediate question of the validity of palaeomagnetic techniques for determining the Earth's palaeoradii. As McElhinny and his colleagues point out, Eggedy (*Geofis. Pura Appl.* **45**, 115; 1960) was the inspiration for the use of palaeomagnetic data as a test for Earth expansion. His first proposal was limited to palaeomagnetic sampling sites on the same palaeomagnetic meridian, but he later (*Nature* **190**, 1097; 1961) suggested a less restrictive technique applicable to palaeomagnetic data generally. In the much improved version developed by Ward (*Geophys. J.* **8**, 217; 1963; **10**, 445; 1966) this 'minimum scatter method' involves the determination, for a single landmass, of palaeomagnetic pole positions for a series of assumed palaeoradius values. The 'correct' palaeoradius is then taken as the one corresponding to the minimum scatter of poles. Unfortunately, in the hands of Ward and others the method achieved only limited success, for at that time palaeomagnetic data were neither accurate nor extensive enough to enable any but the greatest of suggested palaeoradius changes to be detected.

That position has now changed, however, and McElhinny and his coworkers have been able to revive Ward's method in conjunction with palaeomagnetic data capable of resolving the smallest changes in the Earth's radius ever proposed. But irrespective of the quality of the raw data, is Ward's method valid in the first place? McElhinny *et al.* evidently believe that it is; but Carey (*The Expanding Earth*, Elsevier, 1976) has already argued at

great length that it is not. He concludes that the minimum scatter of poles will always occur when the assumed palaeoradius of the Earth is about equal to the present radius; so however good the basic data and however much the Earth's radius has really changed, the application of Ward's method will inevitably lead to the conclusion that the Earth has not expanded at all.

Ward assumes that although the shape of the continents must change slightly as the curvature of the Earth's surface changes, they remain constant in size and the distances and angles used in interpreting the palaeomagnetic data in terms of the palaeoradius also remain constant, when measured from a 'central point'. Ward took as the 'central point' the mean position of the rock units studied; Van Hiltten (*Tectonophysics* **5**, 191; 1967) later took the centroid of the continent; McElhinny *et al.* (who refer to the "continent keeping the same physical dimension") use both the average site location and the "approximate centre of the continental block", discovering in the process that both lead to very similar values of palaeoradius.

Carey contends, however, in a long and involved geometrical argument that during expansion of the Earth a continent will deform in such a way and to such an extent as to make nonsense of any simplified model used in the determination of palaeoradius from palaeomagnetic data. If he is completely right, palaeomagnetism presumably has no role in detecting any possible increase in the terrestrial radius. If he is right in principle but not practice (perhaps because the continental deformation is too small to invalidate Ward's model), palaeomagnetic methods will be acceptable as long as the basic data are good enough. If he is wrong, there is nothing to worry about. The fact is, however, that whether Carey is right or wrong his criticism exists and has apparently never yet been refuted explicitly. Until someone chooses to do so, there must be lingering doubt in the minds of disinterested observers. □

Progress on slime mould morphogens

from Peter C. Newell

ALTHOUGH the cellular slime mould *Dictyostelium discoideum* has yielded a great deal of information about the intercellular signalling involved during the organism's aggregation phase (the phase when the starving amoebae swarm together to form a multicellular body) there has always been the possibility that it would be just as difficult to get one's hands on the intercellular regulatory substances or 'morphogens' that are used during the later stages of morphogenetic development as it has been in more complex embryonic systems. Recent reports from two groups working with *D. discoideum* however, give strong encouragement for a more optimistic point of view.

Three classes of morphogen may be envisaged in this organism. For example, one might be concerned with controlling which of alternative pathways of development are taken, a second with inducing development in general without regard to the cell types formed, and a third with inducing the differentiation of specific cell types. In the first class is the substance that can switch developing aggregates of cells from the sorocarp (stalk and spore)-forming programme to the alternative 'slug' programme. During the slug programme stalk and spore development is held in abeyance while the organism slowly moves over the substratum in search of a more suitable place to develop. The slug is morphologically and behaviourally distinct from the alternative forms of development and is apparently formed in response to an 'awareness' by the developing aggregate of an overcrowded environment. In a recent paper by Schindler and Susman (*J. molec. Biol.* **116**, 161; 1977) the substance that induces formation of this migratory form is convincingly identified as NH_3 . This metabolite is formed in large quantity by developing aggregates as the starving cells rely on the breakdown of endogenous protein for a major part of their energy requirements. The evidence that NH_3 is the regulating agent comes from the finding that, not only does the naturally occurring agent show many of the chemical and physical properties of NH_3 but also that it is mimicked by ammonium carbonate (at a pH above 7.0) when added during the appropriate 'decision-making' period. In addition the slug stage can be omitted entirely if the NH_3 -absorbing system of glutamate dehydrogenase, NADH and α -ketoglu-

tarate is added to the young aggregates. The NH_3 seems, therefore, to be acting as a simple, metabolically produced morphogen that regulates the developmental pathway taken by the organism.

In the second class of morphogen is the inductive signal for differentiation into spores and stalk cells. From work originally performed by John Bonner (*Proc. natn. Acad. Sci. U.S.A.* **65**, 110; 1970) the regulatory substance at this level of control seems to be cyclic AMP. Cyclic AMP causes cells to transform into typical stalk cells without ever aggregating in the normal way. It is also the chemoattractive substance by which starving *D. discoideum* aggregate ready for development. However, in addition to this action there is evidence that pulses of cyclic AMP released during the aggregation process (rather than a continuous signal) are able to switch on some of the very early events of differentiation (Gerisch *et al.* *Nature* **255**, 547; 1975). Moreover, the genus *Polysphondylium*, in which cyclic AMP, although secreted at late stages of aggregation, is not a chemoattractant (this role is taken by a polypeptide instead) is also induced to form stalk cells by added cyclic AMP, (Francis *Nature* **258**, 763; 1975). The two actions of chemotaxis and stalk cell induction are therefore clearly distinct. Until very recently one was tempted to deduce from these observations that cyclic AMP has a specific effect on stalk cell induction. That this is not so is ably shown in the recent paper of Kay, Garrod and Tilley (*Nature* **271**, 58; 1978) who took, as a measure of spore induction, the number of cells induced to form the 'prespore vacuoles' (PSVs) that are characteristically formed during the course of spore maturation, rather than looking for mature refractile spores as previously. Using this criterion of spore pathway induction they found that both spore and stalk cell development was initiated by added cyclic AMP. Spore differentiation differed from that of stalk cells in that the process could not be completed to maturity under these conditions. Thus although cyclic AMP can induce differentiation, it must be a general inducer for the slime mould cells.

Important progress has also recently been made in demonstrating the existence and some of the properties of the specific cell-type inducers that can be considered as the third class of morphogen. The evidence for the idea that cyclic AMP on its own was not sufficient for stalk cell induction came from the work of Town, Gross and Kay

(*Nature* **262**, 7; 1976) who found that the proportion of cells forming stalk cells in monolayers in the presence of cyclic AMP was dependent on the cell population density. The farther apart the cells were separated the fewer stalk cells were formed. Using Cellophane membranes to separate cell layers at different densities Town *et al.* were also able to show that cells at high density on one side of the membrane were able very efficiently to help cells at low density on the other side to develop into stalk cells in the presence of cyclic AMP. The diffusible factor responsible is currently being characterised and preliminary results show that it is a small glycopeptide of 1,000 to 2,000 molecular weight whose biological activity is dependent on sialic acid, N-acetyl glucosamine and L-fucose that are present in its carbohydrate moiety (C. Town, personal communication). Using a similar technique but monitoring PSV formation to identify cells in the spore-forming pathway, Kay *et al.* described in their recent paper that although prespore cell induction is also cell density dependent (suggesting that, again, an endogenous factor is involved) the helping cells are only properly effective if present on the same side of the membrane as the cells being induced. In contrast to the stalk-specific factor the spore induction factor is not, therefore, freely diffusible through such membranes and can only act when cells are in very close proximity to each other.

The relationship between the three classes of morphogen is under active investigation. The area in which most progress has been made so far is that between NH_3 and cyclic AMP. In a model recently proposed by Sussman, Schindler and Kim (In *Development*

A hundred years ago

It is gratifying to know that at last Cleopatra's Needle has safely reached the Thames. It is proposed to moor the ingeniously constructed vessel containing the obelisk at a convenient part of the Thames embankment for some days, to enable the public to inspect it.

From *Nature* **17**, 24 January, 251; 1878.

and Differentiation in the Cellular Slime Moulds (Eds Cappuccinelli, P., Ashworth, J.) 31, (Elsevier/North Holland, 1977)) it was suggested that NH_3 inhibited spore and stalk cell differentiation by inhibiting cyclic AMP production. Recent work of Schindler and Sussman (*Biochem. biophys. Res. Commun.* **79**, 611; 1977) showing that NH_3 (but not NH_4^+) at physiological levels dramatically decreases cyclic AMP synthesis or release in starving cell suspensions and the work of Thadani, Pan and Bonner (*Expl. Cell Res.* **108**, 75; 1977) showing an inhibitory effect of NH_3 on cyclic AMP release by cells of the species *D. mucoroides*, suggest that this conjecture may indeed be soundly based. Whether the effect is indirect or whether NH_3 acts directly on the membrane-bound adenylylate cyclase remains to be resolved. □

Energetic oxygen ions in the magnetosphere

from D. T. Young

MAGNETIC storms are vast disturbances of the Earth's magnetosphere dissipating energy at the rate of 10^{11} – 10^{12} watts over several days. Their connection to disturbances on the Sun was realised more than 100 years ago and it is now clear that solar weather is carried to the Earth by the flow of solar wind plasma past the magnetosphere. Disturbances in the solar wind step up the vast magnetospheric dynamo thereby providing the storm's energy. But basically magnetic storms require the acceleration and transport of large amounts of hot plasma (0.1–50 keV) and it is something of an embarrassment that no one really knows where all this plasma comes from. Does it originate as cold ($\lesssim 0.1$ eV) ionospheric plasma or as relatively hot solar wind (electrons ~ 10 eV, ions ~ 1 keV per nucleon)? Given what is known about magnetic storms and their relation to the solar wind the most reasonable assumption to make is that the hot plasma also originates in the solar wind. That this is not entirely the case has been demonstrated convincingly by the recent observation during three magnetic storms of roughly equal amounts of hot O^+ and H^+ ions (0.5–16 keV) in the magnetospheric ring current (Johnson *et al. Geophys. Res. Lett.* **4**, 403; 1977).

Centred about the equatorial plane, the ring current is an enormous electric

circuit whose current is carried primarily by ions trapped in the geomagnetic field. Although the 'ring' occupies much the same region of space as the Van Allen radiation 'belts' the latter are much less dense and contribute very little net current. Magnetic storms are manifestations of the growth and decay of the ring current as hot plasma is injected into it early in the storm and is then gradually lost, primarily by charge exchange with neutral hydrogen and by scattering into the atmosphere. During storms the plasma particles penetrate deeper into the geomagnetic field and the quiescent ring current (normally centred at altitudes of $\approx 30,000$ km) shrinks down to altitudes of $\approx 10,000$ km. Although Johnson and his colleagues at the Lockheed Palo Alto Research Laboratory obtained data at somewhat lower altitudes ($\lesssim 8,000$ km), the bounce motion of the ions along magnetic lines of force enables them to sample the actual current carriers.

Together with the Lockheed group's earlier report of O^+ and H^+ ions streaming upwards out of the ionosphere (Shelley *et al. Geophys. Res. Lett.* **3**, 654; 1976) their present results have far reaching consequences for models of the aurora and storm-time ring current. Most of these rely heavily on the hypothesis that solar wind plasma enters the magnetosphere by way of the magnetotail on the night side of the Earth. Plasma acceleration and transport deeper into the magnetosphere occurs during the 'collapse' of part of the magnetotail and the accompanying conversion of stored magnetic energy into particle kinetic energy. As the heated plasma is driven deeper into the nightside magnetosphere, the more easily scattered electrons travel down magnetic field lines, bombarding the atmosphere and producing the aurora. Gradients in the geomagnetic field cause the relatively more stable ions to continue drifting in a westerly direction eventually forming the ring current. This explains why what was often called the 'proton' ring current was expected to have solar wind like composition and why it is so disconcerting to find terrestrial ions mixed in apparently large proportion. How the generally accepted hypothesis of plasma transport and acceleration from the magnetotail earthwards will be reconciled with the Lockheed group's observation of ionospheric plasma accelerated in more or less the opposite direction remains to be seen.

Johnson *et al.* obtained their data with one of a new class of particle detectors, the energetic ion mass spectrometer. Only in the past few years has it been technically feasible to build mass spectrometers with the required wide energy and mass ranges (typically

≈ 0 –15 keV per charge and 1 to >30 a.m.u. respectively) within the rigid constraints of low weight and stray magnetic fields demanded of satellite instrumentation. Perhaps the most sophisticated of the new spectrometers was first flown on the ESA GEOS satellite (Balsiger *et al. Space Sci. Instrum.* **2**, 499; 1976) while the more recently launched ISEE-A carries a nearly identical spectrometer built by the Lockheed and GEOS groups together. To appreciate that these instruments are indeed a step forward one need only consider that before 1972, plasma detectors operating between 10 eV and 50 keV were either electrostatic analysers or solid state devices used only to measure particle energy and classify their charge as positive or negative. Since solar wind plasma is known to be $\approx 95\%$ protons the energy-only detectors abetted the hypothesis that the hot magnetospheric plasma originates in the solar wind. With this assumption to go on it was not necessary to measure anything but 'protons'.

Adding to the confusion over magnetospheric plasma origins brought on by the Lockheed results are observations made with the GEOS mass spectrometer of O^{2+} and $^4\text{He}^{2+}$ inferred to be of terrestrial origin (Young *et al. Geophys. Res. Lett.* **4**, 561; 1977). We conclude that the ions are produced at altitudes $\gtrsim 20,000$ km (that is, not the ionosphere) and are accelerated during storms to energies as high as 1 keV. This result is disconcerting because it was long thought that the simplest test for solar wind plasma in the magnetosphere would be the ratio of $^4\text{He}^{2+}$ to protons. This is about 0.04 in the solar wind and, before GEOS, the terrestrial value at keV energies was thought to be orders of magnitude smaller. The $^4\text{He}^{2+}$ ion is even further compromised as a tracer because it is converted rather quickly by charge exchange to $^4\text{He}^+$. As tracers one is apparently left only with more exotic (and difficult to measure) solar wind species such as O^{6+} and ^3He . The latter has in fact been detected inside the magnetosphere by the foil collection technique.

Mass spectrometers have been something of an ugly duckling in magnetospheric research. Initially too heavy, magnetically dirty and ill suited for hot plasma measurements, they have come of age and are now invited to all the best satellite projects. The GEOS-ISEE type spectrometer will be flown on GEOS2 scheduled for launch this year, and is included on NASA's next magnetospheric research satellite the Dynamics Explorer. It therefore seems likely that energetic ion mass spectrometers will have the opportunity to supply a few answers to the many questions they have been raising lately.

Thermonuclear reactions confirmed in laser-driven fusion

from Derek Beynon

THE central concept in inertial-confinement fusion is the implosive compression of deuterium-tritium fuel to densities and temperatures where a significant number of thermonuclear reactions will occur. Throughout the world a number of experimental programmes exist to investigate the capacity of powerful lasers, relativistic electron beams and, latterly, heavy-ion beams to achieve this mode of fusion. The ideal compression should occur isentropically in an ablatively imploded pellet of cryogenically solid deuterium-tritium mixture with a final density compression of about 10^4 in order to achieve an energy 'break even' where the resulting fusion energy equals the laser input energy (*Nature* **239**, 139; 1972). Because of the power output limitations of the present generation of large neodymium glass or CO₂ lasers, which give up to 10^{14} – 10^{16} W cm⁻² on target, experiments have been limited to 'exploding pusher' targets which are glass microshells, typically 90 μ m diameter, with 1 μ m wall thickness, containing an equimolar deuterium-tritium gas mixture of density 2–2.5 mg cm⁻³. Producing a non-isentropic compression, the whole of the glass shell heats rapidly before it moves to push the enclosed gas to about normal solid densities. The resulting ion temperatures, 4–6 keV, should according to predictions allow the thermonuclear reaction

to proceed, with a very small contribution from the D–D reaction. Using such targets a group from the Lawrence Livermore Laboratory (LLL) reported at the 11th European Conference on Laser Interaction with Matter (Oxford, September 1977) that neutron yields in excess of 7×10^8 per laser shot had been achieved using the Argus neodymium glass laser facility.

Although the performance of such targets may not be very representative of ablatively driven systems they are of particular value in allowing detailed computer predictions of laser plasma interactions and magnetohydrodynamics to be checked experimentally. One question of fundamental importance which needs to be answered is whether these relatively high yields of neutrons

and α -particles are truly thermonuclear in origin or whether they are produced by fusion reactions between deuterium and tritium ions which have been accelerated to high energies within the plasma. Thermonuclear-produced particles are expected to be produced centrally in the compressed plasma whose ions have a maxwellian energy distribution at a temperature T_i (keV) giving rise to a gaussian-like energy distribution of neutrons and α -particles with a width (fwhm) of $\Delta E = 177\sqrt{T_i}$ (keV). Fusion products which are non-thermal in origin will have a different width ΔE depending on the details of the accelerating mechanisms. Early work by Rose *et al.* (*Nature* **181**, 1630; 1958) demonstrated the existence of non-thermonuclear fusion neutrons produced by the magnetic confinement device Zeta. McCall *et al.* (*Phys. Rev. Lett.* **30**, 1116; 1973) have postulated a detailed mechanism where the production of fast electrons by the resonance absorption of the laser light results in an electrostatic field on the outside of the compressed zone of the deuterium-tritium mixture. For nanosecond laser pulses a low density low temperature corona will be generated around this compressed zone before significant fast electron production occurs. As electrostatic acceleration occurs near the critical surface, where the plasma and laser light frequencies are equal, fast ions pass through the corona generating neutrons and alphas. For picosecond laser pulses, however, no low density plasma region is produced and the fast ions produce no particles. The non-thermonuclear particle production should therefore depend sensitively on the pulse characteristics and the comparisons with experiments made by McCall and others at Los Alamos would indeed seem to confirm this. The beam properties of the ions will now produce energy distributions of neutrons and alphas which differ significantly from the gaussian distribution associated with thermonuclear reactions. For example an equimolar monoenergetic D–T ion beam of energy E_i (keV) uniformly converging on a cold D–T target would result in a square distribution of neutrons and α -particles with a width $\Delta E = 150\sqrt{E_i}$ (keV).

Over the past 2 years a series of elegant experiments at LLL has confirmed the thermonuclear origin of the neutrons and α -particles produced in exploding pusher targets. The initial set of experiments (*Phys. Rev. Lett.* **35**, 1083; 1975) used a time-of-flight technique to obtain the energy distribution of the 3.52 MeV α -particles. By measuring the transit time $t = d/v$ over a flight path of length d of an α -particle of velocity v , the α -particles' energy dispersion $\Delta E = 2E(v/d)\Delta t$ is

obtained for a temporal resolution Δt . The experiment, designed so that α -particles in the range 2.6 to 3.9 MeV were magnetically deflected and detected by a scintillator, measured a dispersion consistent with a maxwellian temperature of 2.2 keV for the first laser shot and 3.0 keV for the second. This should be compared with maxwellian values in the range 1.6–3.0 keV calculated by numerically modelling the imploding microshells with a two dimensional Lagrangian hydrodynamics code. However such experiments are by no means conclusive since they assume that the α -particles are produced inside the glass microshells and consequently rely on a 0.2 MeV computed energy correction for the energy loss of the α as it passes through the compressed gas and the glass walls of the microsphere.

Consequently the Livermore group evolved an entirely novel approach to resolve the spatial distribution of the α -particles as they are born in the thermonuclear process by directly imaging the thermonuclear burn region within the target with a resolution of about 10 μ m. (*Phys. Rev. Lett.* **39**, 22; 1977). The technique, which is essentially a holographic one, was originally proposed for stellar X-ray imaging and has a number of applications in nuclear medicine (*J. Nuclear Med.* **13**, 382; 1972). It proceeds in two stages. In the first the radiation source to be imaged casts a shadowgraph (a coded image) through a Fresnel zone plate (a coded aperture) onto a suitable detector, in this case a thick cellulose nitrate film. The image reconstruction is achieved at the second stage when a negative of the shadowgraph is illuminated with coherent light to produce a Fresnel diffraction pattern which is a reconstruction of the original α -source distribution but inverted and magnified. With associated neutron yield measurements this technique showed that more than 97% of the α -particles originated in a central region, ovoid in shape, which had a diameter about one-third that of the original target.

Final confirmation of the thermonuclear origins of the neutrons and, by inference, of the α -particles has now been obtained at Livermore (*Appl. Phys. Lett.* **31**, 645; 1977) using high resolution time-of-flight spectrometry on the neutron yield. Since there is negligible interaction of the emerging neutrons with the glass microsphere and its contents, measurement of the neutron energy distribution is a particularly useful diagnostic. Using 44.5-m flight paths with fast plastic scintillation detection, a mean measured neutron energy of 14.00 ± 0.10 MeV from five experiments compares well with the expected value of 14.05 MeV. Interpreted in terms of maxwellian ion temperatures the measured energy dis-

tributions correspond to a range of temperatures from 5.2 to 6.3 keV, in excellent agreement with the predicted thermonuclear value of 5 keV.

The prevalence of chaos

from N. MacDonald

It has been known since the time of Poincaré that quite simple conservative dynamical systems, such as two coupled linear oscillators, can exhibit highly complicated behaviour. As well as periodic trajectories, which are closed curves in phase space, there are also trajectories which, loosely speaking, fill up volumes in phase space. The rather special nature of conservative systems limits the number of physical contexts in which this behaviour can be manifested. (For some interesting examples see Henon & Heiles *Astr. J.* **69**, 73; 1964; Dunnett, Laing & Taylor *J. math. Phys.* **9**, 1819; 1968.) Analogous behaviour has been observed in recent years in a number of nonlinear models of physical systems which are open or dissipative, rather than conservative. This is leading to reappraisal of our understanding of these systems.

The best known example is that put forward by E. N. Lorenz (*J. atmos. Sci.* **20**, 130; 1963). He starts from the partial differential equations for flow in a layer of liquid of uniform depth with a constant temperature difference maintained between the upper and lower surfaces. These have a steady state solution with zero flow. As the temperature difference is raised this solution becomes unstable and convective flow solutions replace it. Lorenz examines one particular mode of convective flow, and uses a truncated Fourier expansion to reduce the problem to one involving three coupled ordinary differential equations. The variables are the intensity of convective flow, the temperature difference between ascending and descending currents, and a quantity measuring the departure from linearity of the temperature gradient across the fluid layer. Lorenz finds a second instability, beyond which the simple smooth convective flow is replaced by an extremely complex and unpredictable flow. The mathematics of this situation have become popular in the past few years, and progress in understanding the nature of the complex flow is reviewed in the proceedings of a seminar

N. MacDonald is in the Department of Natural Philosophy in the University of Glasgow.

The blind fishes of Persia

THE note published in *News and Views* (**264**, 113; 1976) on the blind cave fishes of Persia mentioned the discovery of the two cavernicolous forms *Noemachilus smithi* (Cobitidae) and *Iranocypris typhlops* (Cyprinidae) in the same well-like outlet. This is of great interest for the zoogeographical and etho-ecological interpretation of the possible mechanisms which led epigeic fishes to colonise subterranean waters and evolve underground into isolated homogeneous populations composed entirely of eyeless and depigmented individuals. These phenomena of regressive evolution have been well studied on several populations inhabiting caves (Thinès *L'évolution régressive des Poissons cavernicoles et abyssaux*, Masson, Paris, 1969), but little, if any, specific attention has been given to the case of cavernicolous forms found in wells and artificial outlets. It is therefore fortunate that Mr Smith was able to discover this new *Noemachilus* form in association with the previously discovered *Iranocypris* (Brunn & Kaiser *Dan. Scient. Invest. Iran*, Munksgaard, Copenhagen, 1943). However, the coexistence of two distinct regressed species in the same well has been observed before. In 1962, Mees found two different blind and depigmented Teleosts, *Milyeringa veritas* (Gobiidae) and *Anommatophasma candidum* (Synbranchidae) in two wells depending on the same subterranean system and located about 10 miles apart, near Yardee Creek Station, North West Cape, Australia (Mees *J. R. Soc. West. Austr.* **45**, (I), 24; 1962).

The coexistence of distinct cavernicolous forms in a same biotope other than a cave, raises the question of the exact nature and extent of their habitat. Underground waters can be traced with sufficient precision in many karstic systems (the system of sinks, underground caverns and streams found in limestone areas), whereas water sheets feeding wells or pumping sites do not lend themselves to similar descriptions. In addition, such phreatic water tables cannot be explored by speleologists, so that the only topographical data are those furnished by geological surveys. Thus, biospeleologists have had to limit themselves to inference as far as the

habitat is concerned. The only sound hypothesis about regressed fishes found in wells and other artificial water outlets is that these forms normally live in the phreatic sheets and are occasionally attracted to zones exposed to light by organic remnants of animal or human origin. The fact that fishes of the same species are sometimes observed in wells separated by a great distance is, in my opinion, the strongest argument in favour of this view. Mees reported the presence of the free-swimming *Milyeringa* in only two of the three wells he visited (*Milyering*, Kudmurra and Tandabiddi, the last halfway between and some 10 miles from the other two), whereas the eel-like *Anommatophasma* was found in all three sites. The cases of *Iranocypris typhlops* and of *Noemachilus smithi* seem similar to that of *Milyeringa veritas*. The ecological conditions in which these fishes live are moreover similar to those reported as early as 1904 by Goeldi for *Phreatobius cisternarum* (Goeldi *Rept. 6th Int. Zool. Congr. Bern*, 549; 1904), a very peculiar catfish belonging to the family Trichomycteridae which he found in a cistern of Marajo Island in the mouth of the Amazon and which was rediscovered recently (Delamare, personal communication). I have collected specimens of the blind Clariidae *Uegitglanis zammaranoi* in the canalizations of the Ischia-Baidoa pumping station (Somaliland) some 60 miles from the well of Uegit, where the first specimens were discovered in 1923 by Gianferrari (*Atti. Soc. Ital. Sc. Nat. Mus. Civ. Stor. Nat. Milano*, **62**; 1923). To the present day, this distance is by far the greatest to have been reported for the geographical extension of a cavernicolous fish not dwelling in a cave (Thinès *Rev. Zool. Bot. Afric.* **57**, 117; 1958). The case of *Noemachilus smithi* can thus be considered as a typical instance of an already well-known phenomenon, whose meaning for biospeleological research is clear.

G. THINÈS

CPEC Animal Behaviour,
Louvain University
3041 Pellenberg
Belgium

on turbulence held at Berkeley in 1975 (Springer Lecture Notes in Mathematics No. 615; 1977.)

The conditions for this new instability are physically unattainable in this experiment. However, H. Haken has

pointed out (*Phys. Lett.* **53A**, 77; 1975) a remarkable parallel between the Lorenz model and a classical approximation to the dynamics of a single mode laser. In this case the three variables are the field strength and polar-

isation of the radiation, and the inversion of the atomic levels. The second instability can be attained if the laser cavity loss is high enough. Haken identifies this instability with the onset of undamped spiking of the laser output.

These models are purely deterministic, being set up in terms of ordinary differential equations. Yet the solutions behave in an apparently random way. The term 'chaos' has been appropriated to refer to this intriguing feature of nonlinear dynamical systems of three or more dimensions. A beginning has been made in the classification of different types of chaotic flow, and the determination of the conditions under which they occur. In a fascinating series of papers (*Z. Nat.* **31a**, 259, 1168, 1664; 1976; **32a**, 607; 1977) O. E. Rössler outlines some of the taxonomy of chaotic flows, and sketches a number of potential applications.

To visualise one possibility, think of a conical spiral seashell with a central pillar, and imagine a line winding out along the expanding spiral until it reaches the mouth of the shell, then tucking itself into the pillar and re-injecting into the narrowest coil. The equivalent behaviour is impossible for the trajectory of a dynamical system in two dimensions, because it would require that the trajectory cut itself at a point which is not a point of equilibrium. This kind of spiral trajectory could of course be periodic. The essential new thing about chaos is that for some sets of nonlinear equations all such periodic trajectories are unstable. The majority of trajectories then behave as if repelled, not only by the unstable focus at the point of the shell, but by each of the unstable periodic trajectories. Each time a trajectory re-injects to somewhere near the point it emerges in a different direction.

One may invent other varieties, for example two unstable foci with reinjection from the outside of each spiral to an inside coil of the other. H. Haken and A. Wunderlin (*Phys. Lett.* **62A**, 133; 1977) have given a simple geometric picture of the Lorenz-laser chaotic flow.

Rössler's extensions of the applications of chaotic flows have mainly been to schematic models of chemical reactions, involving oscillating and switching components. He has also discussed the relevance of this topic to the Rashevsky-Turing model of morphogenesis as controlled by chemical reactions and diffusion between cells. In a recent issue of this journal (*Nature* **271**, 189; 1978) Rössler and K. Wegmann propose the application of these methods to the Belousov-Zhabotinskii oscillating reaction (for a recent review see Tyson *The Belousov-Zhabotinskii Reaction* (Springer Lecture Notes in

Biomathematics No. 10; 1976)).

When this reaction is studied in a well-stirred solution, oscillations of the chemical concentrations, with well-defined period, can be detected by colour changes in an appropriate indicator. Also when the solution is in a shallow dish and unstirred, waves of colour change can be observed on the surface. A. Winfree suggested (personal communication to Rössler) that some of his observations on these waves might indicate symptoms of chaos. Rössler and Wegmann now report observations of the electrochemical potential in a well-stirred Belousov-Zhabotinskii reaction. This shows irregular spiking over times of the order of an hour, with about three spikes every 2 minutes. They suggest that this may be related to a particular type of chaos, which they illustrate by computed solutions of a very simple set of equations

$$dx/dt = -y - z$$

$$dy/dt = x + 0.55y$$

$$dz/dt = 2 - 4z - xz$$

Even this apparently innocent set of equations, in which there is only one nonlinear term, have rich possibilities. They can exhibit the 'seashell' type of chaos as well as the type which Rössler and Wegmann consider may be present in the Belousov-Zhabotinskii experiment. The authors point out that simultaneous measurements of two or more quantities can give a much more critical test of their hypothesis, and comment briefly that they have some promising results, plotting the electrochemical potential against the potential of an electrode sensitive to bromide ions.

Other authors (Schmitz, Graziani & Hudson, *J. Chem. Phys.* **67**, 3040; 1977) have reported data on the well-stirred Belousov-Zhabotinskii reaction consistent with a different type of chaotic flow while L. F. Olsen and R. Degn (*Nature* **267**, 177, 1977) have presented evidence for chaotic flow in the horse-radish peroxidase reaction. It is thus becoming apparent that even without the manifest complications brought in by considering diffusion as well as reactions, these systems reveal a rich variety of phenomena. This will undoubtedly stimulate much further work, both theoretical and experimental, on chemical oscillations and on their possible bearing on biological problems.

Natural fission reactors—Oklo style

from S. A. Durrani

A Technical Committee Meeting (Experts Group) on Natural Fission Reactors was held at Paris on 19–21 December 1977. It was organised by the International Atomic Energy Agency (IAEA) in collaboration with the French Atomic Energy Commission (CEA).

AFTER 5 years of investigation into the Oklo phenomenon, it is no longer a question of why it happened but why it should not have happened all over the world. Several researchers have been hunting for clues at likely places but as yet no other natural fission reactors have turned up.

The Oklo phenomenon (see *News and Views* **256**, 264; 1975), was first discovered by French scientists in 1972 when they established that a self-sustained chain reaction had occurred in a uranium mine, some 1,800 Myr ago, at Oklo in the Republic of Gabon in west equatorial Africa. The higher natural abundance of ^{235}U , namely over 3%, prevailing at that time (more than two half-lives ago for the isotope), the moderation of the fission neutrons by soil water (making it more likely that they would initiate new fission reactions), and effective absence of neutron-absorbing 'poisons', constituted favourable conditions for the occurrence of a self-propagating fission reaction. Many of the fission products, in proportions exactly the same as those obtained in today's man-made reactors, still lie there as evidence of the long-ago activity. That in itself was an important discovery, with far-reaching implications for the storage of nuclear waste.

The Paris meeting of the Technical Committee on Natural Fission Reactors (Experts Group), convened jointly by the International Atomic Energy Agency (IAEA) and the French Atomic Energy Commission (CEA), was the first of periodic conferences on the subject recommended to be held by a permanent international working group on Natural Fission Reactors (NFRs) set up under the auspices of the IAEA following the 1975 conference at Libreville in Gabon. Over 40 papers were presented on topics ranging from the geology and petrology of the Oklo reactor materials to isotopic chemistry, radiation damage studies of samples from a reaction zone and its surroundings, reactor physics

S. A. Durrani is a Senior Lecturer in the Department of Physics, University of Birmingham, UK.

models of the NFRs, and the role of organic materials in concentrating the initial uranium ore deposits.

The opening address was delivered by R. Naudet (CEN, Saclay), the scientific secretary of the meeting and since 1972 the director of the 'Franceville Project' established by the French CEA to promote and coordinate the international investigation of the NFR phenomenon. He reported on the 5 years of exploration of the Oklo site and of the international ramifications of the project. In the papers that followed, the emphasis was on natural fission reactors in the plural—not only at Oklo but elsewhere in the world. The development of the phenomenon was traced (or imagined) in both time and space. Investigations have shown that there was not just one reactor at Oklo: at least six 'reaction zones' over a relatively small area (a few thousand square metres) have been identified. A question exercising not a few minds was whether one of these was a 'primary' reactor and the others either secondaries or its lineal descendants. The reactors, like reproducing organisms, seem to have been 'propagating' themselves. Naudet, in true detective story style, termed this the 'Oklo mystery'. The age of the phenomenon has now been put back from $\sim 1,800$ Myr to nearer 2,000 Myr; the duration of the entire drama at Oklo, from the first spark to the last smolderings of the atomic fuel has also been extended from $\sim 500,000$ years to ~ 2 (or perhaps several) Myr.

A systematic search for other natural fission reactors is now being conducted elsewhere in the world, as described by K. E. Apt (Los Alamos Scientific Laboratory). Apt and his colleagues have analysed high-grade pre-Cambrian uranium ores from Australia, Canada, South America, Africa and the USA, for tell-tale isotopic variations in uranium and its fission products. No isotopic anomalies, indicating criticality, have so far been discovered in the samples from any of those sources. But, as was evident during discussion, everyone now expects another natural fission reactor to be discovered in some part of the world sooner or later. The hunt is on.

Amongst the papers on physico-chemical aspects of the phenomenon were those on estimation of the reactor temperature (~ 280 – 400°C) by P. Holliger and colleagues (CEN, Saclay) and R. Vidale (Los Alamos Scientific Laboratory); gauging the adverse effect of intense radiation on the thermoluminescence properties of Oklo materials inside the reaction zone by S. A. Durrani and colleagues (University of Birmingham); problems of criticality and reactor control in Oklo and other NFRs by R. Naudet; and geochemical study of insoluble organic

material (kerogene) of the Oklo uraniferous ore by M. Vandenbroucke and colleagues (Institut Français du Pétrole).

A final round table discussion focused on the relevance of the Oklo experience to present-day problems of nuclear waste storage. G. A. Cowan (Los Alamos Scientific Laboratory) reported evidence for the remarkable stability of uraninite (UO_2) grains at the Oklo reactor site. He estimated fractional loss rates of 10^{-10} yr^{-1} for elements such as uranium and plutonium. Even for the most volatile

elements, the loss rates during the operating period of the reactor were unlikely to have exceeded $\sim 10^{-6}\text{ yr}^{-1}$. D. G. Brookins (University of New Mexico) demonstrated that many of the fission products (the rare earths, for example) had hardly migrated from the host pitchblende and its associated gangue over the past $\sim 2 \times 10^9$ yr. These observations greatly strengthen the case for the storage of long-lived nuclear waste products (such as plutonium) in tectonically stable geological repositories, possibly after incorporating them in synthetic uraninite matrices. □

Telescopes of the future

from Edward Kibblewhite and John Whelan

The ESO Conference on Optical Telescopes of the Future was held at CERN, Geneva on 12–15 December, 1977.

CONTINUOUS improvement of detectors has enabled astronomers to use the light collected by telescopes more efficiently and to observe fainter objects in shorter times without building bigger telescopes. L. Woltjer (ESO, Geneva), in opening the conference, pointed out that the 'collecting power' of telescopes (area of mirror times quantum efficiency of detector) has doubled every 7 years since 1910. Since the next generation of detectors will approach quantum efficiencies of unity in the near future, the only way to improve collecting power is to build telescopes of bigger effective mirror area.

However, I. King (ESO), R. Ekers (Gröningen) and M. Disney (University College, Cardiff) arguing from different standpoints, showed that, when observations are background-noise limited, the important scaling factor for signal-to-noise detection efficiency is diameter of telescope (D)/seeing disk size (S). Only high-resolution spectroscopy, which is photon noise limited, scales at D^2 . Some parts of the conference were concerned with increasing D and others with decreasing S . The cost of a telescope system (including dome, computer and so on) using current design scales as D^γ where γ was said to be between two and three; to build large telescopes therefore requires new designs to keep the cost down.

Two telescopes, which are to come into operation shortly, showed that low mirror weight can give great savings in

cost. J. Ring (Imperial College, London) described the new SRC 3.84-m infrared telescope being built in Hawaii. This uses a very thin mirror and a light mounting and cost £2.5 million, one-fifth to one-half the cost of a conventional telescope of the same aperture. P. Strittmatter and colleagues described the SAO/University of Arizona multiple-mirror telescope (MMT). This consists of a rigid frame holding six 1.8-m telescopes which converge the light to a common focus. Each telescope can be moved individually under computer control, and is aligned by looking at a bright star and analysing the image at the focus by computer. With all telescopes aligned, a 0.8-m telescope in the middle of the array, which also acts as a guider, produces a set of parallel laser beams which maintain the alignment of the six telescopes with respect to each other. The MMT will produce $\frac{1}{2}$ arc s images over a 1 arc min field of view, though it is primarily to be used for on-axis work (about 80% of the observations at a typical observatory are on-axis). The structure is alt-az mounted and the whole building rotates. The MMT, which contains many important innovations in telescope design, is said to cost \$8 million and has an equivalent aperture of 4.5 m.

Kitt Peak presented four designs for the 'next generation telescope' (NGT), each providing a 25-m equivalent aperture. A rough cost of \$10⁹ was mentioned—the cost of the Very Large Array (VLA). One design, the 'Shoe', involved a rotatable sector of a large spherical mirror, like part of the Arecibo radiotelescope, the spherical aberration being corrected by auxiliary optics. Other proposals were an enormous steerable dish made out of a mosaic of mirrors, an MMT design

Edward Kibblewhite and John Whelan are at the Institute of Astronomy, Cambridge.

with six 10-m telescopes, and the 'singles array', in which six 10-m telescopes would feed a central coude focus (see picture). The engineering problems of building a steerable telescope of 25-m diameter were felt to be serious; furthermore the large 'plate scale' (mm per arc s) makes the telescope incompatible with modern detectors. Simultaneous guiding of several smaller telescopes does not seem to be a problem; a suggestion to use accurate gyroscopes to achieve this was made.

Various siderostat telescopes were proposed which have a fixed telescope fed by a larger flat. A. Meinel (Optical Sciences Center, Arizona University) described one with a 45° flat and R. Bingham (Royal Greenwich Observatory) a neat alt-alt design. W. Richter (ESO) proposed a novel telescope which used a giant windmill, both to protect the undomed telescope from wind vibration and also to generate 300 kW of power! A continuing theme throughout the discussion, and emphasised particularly by E. Becklin (NASA, Hawaii) was the need to provide for adequate infrared capability.

At present, observing time on large telescopes is heavily oversubscribed. Disney has, for some years now, proposed incoherent arrays of telescopes in which information is collected by detectors and combined afterwards. He suggested a group of telescopes all identically instrumented which could either all point at one object or act independently. The availability of essentially noise-free detectors now makes this scheme very attractive from an astronomical point of view.

The importance of obtaining greater efficiency by improving the effective seeing disk size was not overlooked during the conference. One uncertainty concerning large (≤ 10 -m) mirrors is whether temperature effects across the mirror would worsen the seeing. Meinel claimed this was already significant. For the proposed space telescope the 'seeing' disk will be about one-tenth that of a good ground-based site and it is this feature which allows it to go so faint. Interesting papers were given by F. Dyson (Princeton University) and J. Hardy (ITEK Corp., Lexington) on the use of active optics to compensate for seeing by deforming the telescope mirror itself or the wavefront near the focus. Hardy showed data from a 1.5-m telescope in which active optics had reduced the seeing disk by a factor of two or three. The technique is probably restricted to bright stars.

The remainder of the meeting was devoted to ground-based optical interferometric techniques for obtaining ex-

Rift Valley fever

from Arie J. Zuckerman and David I. H. Simpson

RIFT Valley fever or enzootic hepatitis is a severe viral infection which primarily affects sheep and cattle causing many deaths in pregnant and newborn animals. The disease occurs naturally only in Africa and by 1912 it was recognised in the Rift Valley in Kenya. The infection is mosquito-borne and the virus, a member of the Bunyamwera group of arbovirus was isolated and identified in 1931. It was then also recognised that many infections occur in man, particularly by direct contact with sick animals or carcasses. Laboratory infections have also been reported. In 1950-51 an epidemic of the disease occurred in South Africa during which it is estimated that 20,000 persons became infected and 100,000 sheep and cattle died from the disease. Another severe epidemic occurred in the central regions in Southern Africa in 1975 (Van Velden *et al.* *S. Afr. med. J.* **51**, 867; 1977).

In October and November 1977 an outbreak of Rift Valley fever occurred for the first time in Egypt in the Nile delta. The number of human cases has been estimated at 10,000-20,000 with 70-80 deaths. In the areas most affected in the provinces of Sharqia Qalyub and Giza as many as 70% of the population were infected (*WHO Wkly. Epidem. Rec.* **53**, 1; 1978). The disease in man usually follows a transient febrile course with severe headache and bodily pains. Complications include haemorrhage, encephalitis and involvement of the eye with macular degeneration and temporary or permanent blindness. Haemorrhage generally indicates a

poor prognosis and autopsy of cases revealed necrosis of the liver associated with haemorrhage, tubular necrosis of the kidneys, pulmonary congestion and haemorrhages in the stomach and colon.

Experimentally lambs are highly susceptible and may die from massive necrosis of the liver within 36 h of infection. Mice die with hepatitis within 3 days, and other laboratory rodents are readily infected. Monkeys develop a mild fever. The pathological lesions are principally those of massive hepatitis in lambs and focal lesions of the liver in older sheep. There is often damage to kidneys, and there may be haemorrhages in the intestines and elsewhere.

In the entomological investigations undertaken in the affected areas in the recent epidemic in Egypt virtually only *Culex pipiens* was found and indeed the virus was isolated from this species of mosquito. People using mosquito nets or otherwise avoiding exposure to mosquitoes at night were apparently not affected. As before, contact and slaughter of sick animals is considered to have caused at least some human cases. While it will be extremely difficult to establish the exact origin of the outbreak it may have resulted from the smuggling of camels (*WHO Wkly. Epid. Rec. op. cit.*). This epidemic illustrates once more that viral infections know no boundaries.

Arie Zuckerman and David Simpson are in the Department of Medical Microbiology at the London School of Hygiene and Tropical Medicine.

tremely high spatial resolution. Hanbury Brown (University of Sydney) gave a critical review of intensity versus Michelson interferometry and concluded that, although his intensity interferometer had achieved all its aims it was probably not competitive with a Michelson for faint objects. This is mainly because the bandwidth of a Michelson is so much greater than that of an intensity interferometer. A. Labeyrie (CERCA, St Vallier-de-Hiery) has made great progress in this area and showed pictures and results of his Michelson interferometer which uses two 25-cm telescopes separated by 20 m. He also described the construction of novel and cheap 1.5-m tele-

scopes to be used in a much more ambitious set-up. C. Townes (University of California, Berkeley) described a heterodyning interferometer for use in the infrared. Several papers discussed various aspects of speckle interferometry which now appears to have become a standard technique.

A. Boksenberg (University College, London) gave a comprehensive and well-organised review of trends in detector development and some astronomical stories were related by J. Greenstein (Caltech). We were also treated to L. Goldberg's (Kitt Peak) visit to China and a tour of the 400 GeV accelerator, which rounded off an extremely successful conference.

review article

Plasma waves in the magnetosphere

D. J. Southwood*

A large variety of plasma wave phenomena are seen in the Earth's magnetosphere. Attempts at the theoretical explanation have had some successes, including wave induced loss of radiation belt particles and the Kelvin-Helmholtz instability source of geomagnetic pulsations. But there are also areas where theory needs more development: for example, on the ion wave turbulence seen on auroral magnetic flux tubes, the role of anomalous resistivity and the origin of the terrestrial kilometric radio waves.

THE Earth's magnetosphere provides a vast variety of plasma wave phenomena over nine decades of frequency ranging from hydromagnetic waves at 1 mHz, whose field at ground level was first detected more than one hundred years ago¹, up to the radio waves near 1 MHz which make the Earth at times the brightest radio planet in the solar system².

The plasma in the magnetosphere is collision-free and 'anomalous' transport effects may be caused by plasma waves and turbulence. Some waves, by contrast, are a secondary effect, but they are still interesting for the information they give about the state of the plasma that supports them. In fact because space exploration has provided much knowledge of the variety of background conditions, the magnetosphere has been a good testing ground of collision-free plasma theory³. There have been notable successes but also some surprises. Here we review some recent examples from both classes.

The background plasma

The plasma distribution in space and energy is crucial in determining what waves occur in a plasma and it is appropriate to start by a discussion of this.

The basic distributions of plasma in the magnetosphere can be rationalised by recognising the dominant role of solar wind driven convection. Because the charged particle Larmor orbits about **B** are much smaller scale than any gross feature except near the neutral sheet in the tail and at the magnetosphere boundary, everything is ordered as illustrated in Fig. 1 by magnetic flux tube. To a first approximation, any two particles remain gyrating about and bouncing back and forth along the same tube as each other throughout the convective motion. In fact we can think of the flux tubes themselves as moving, carrying particles along with them.

The magnetosphere forms an obstacle to the solar wind plasma streaming from the sun and a bow shock forms. Between the shock and the magnetopause boundary is the turbulent magnetosheath. Much of the sheath plasma is deflected around the magnetosphere but direct entry occurs in the cusp region and remnants of this plasma are swept back into the high latitude tail as the plasma mantle. Convection over the polar caps is tailwards, so that in the tail the plasma flows inwards towards its centre plane from both sides. In the centre of the tail is a weak field region, the neutral sheet, with a strong current. Field lines are 'broken' here by the reconnection process and emerging from this region with a sunward flow is a hot plasma with temperature 1–2 keV and density of a few particles cm⁻³ called the plasma sheet. This hot plasma trapped in the Earth's

magnetic mirror field geometry flows inwards and drifts around the Earth to become the 'ring current' plasma, so called because of the depression in magnetic field it produces on the ground at the Earth. Throughout the ring current/plasma sheet the average proton energy exceeds the electron energy by about a factor of 2.

Within this region, in an ideal picture, is a region corotating with the Earth, the plasmasphere. This contains relatively cool plasma (temperature < 1 eV) with high density ($\sim 10^{-3}$ m⁻³) which is in equilibrium with the ionosphere. In a steady convection pattern ring current protons can penetrate the plasmasphere while hot electrons do not. This is because hot particles, as well as their convective 'flux tube' motion, have drift that is dependent on energy and charge.

As well as the ring current and plasmasphere populations the inner magnetosphere also contains the very energetic particles (energy up to MeVs in the inner zones) which constitute the Van Allen radiation belts. This energetic tail of the distribution plays little part in convection though their distribution is understood largely in terms of their injection and diffusion inwards by fluctuations in the convection system.

Several natural features of the convection system deserve

Fig. 1 An idealised view of the noon-midnight meridian magnetosphere. Broad arrows indicate the convective motion of flux tubes. The whole flux tube of plasma down to ionospheric heights moves together except in a region on the dayside magnetopause and in the tail neutral sheet where flux tubes are broken by a process called reconnection. The diagram is not to scale. The tail is very extended (~ 500 – $1,000 R_E$ (Earth radii)).

*Blackett Laboratory Imperial College of Science and Technology, Prince Consort Road, London SW7 UK

note at this point. Because flux tubes move as a whole, stresses are transmitted from the equatorial regions of field lines to the ionosphere and this is done by field aligned currents, 'Birkeland' currents, which may be carried by beams of particles. Birkeland currents have been detected near the outer boundary of the plasma sheet on high latitude field lines which map to the neutral sheet region, and it is also widely believed that the primary particles providing the discrete auroral displays (thin bright arcs) originate from this region. A second layer of Birkeland current oppositely directed to the high latitude set is found at lower latitudes and maps to the region occupied by the hot ring current/plasma sheet plasma. Plasma sheet electrons are regarded as the source of the steady 'drizzle' of electrons into the ionosphere that gives rise to the relatively structureless aurora, the diffuse aurora seen equatorward of the thin arcs.

The next point to note is that the convection system naturally provides both a heating of the hot plasma as it convects Earthward on the nightside and an increase in pressure anisotropy (pressure perpendicular to \mathbf{B} > pressure parallel to \mathbf{B}). Finally a curious feature of energetic particle motion in the convection system is that the protons which best penetrate the plasmasphere are those with 10–20 keV energy, so that just inside the plasmasphere proton distribution functions occur with an absence of lower energy particles.

The convection can thus generate strong currents parallel to \mathbf{B} , particle beams, pressure anisotropies and particle distributions with a 'hole' at low energies (that is non-monotonic energy distributions). It also provides steep spatial gradients in particle distribution. Any of the preceding effects can provide a source of free energy which may drive instabilities or a steady spectrum of plasma waves. Often one envisages a quasi-steady situation where a relatively unchanging wave amplitude is sustained by convection or similar process providing energy at the rate wave energy is lost by some dissipative process such as bad ionospheric reflection.

Lastly note that convection is in fact 'gusty'. The most obvious manifestation is the substorm phenomenon when the auroral pattern breaks up, reconnection in the tail increases and convection and all its attendant phenomena intensify.

The above gives an outline of how the magnetospheric plasma distributions are set up, and as further background it is useful to note here some of the features of the characteristic frequencies that occur in plasma wave theory. The frequency at which protons gyrate about the magnetic field \mathbf{B} , the gyro- or cyclotron frequency, f_p^+ is proportional to the field B ($\approx 0.015 B$ Hz with B in gamma, $1\gamma = 10^{-9}T$) and in the equatorial plane ranges from a fraction of a Hz in the weak tail field to about 10 Hz in the inner magnetosphere. The corresponding electron cyclotron frequency, f_p^- ranges from a fraction of a kHz to a few tens of kHz in inner regions. The plasma frequency, f_p , the frequency at which electrons naturally oscillate about the ions in a cold plasma, is proportional to the square root of the electron density, n . In fact $f_p = 9\sqrt{n}$ Hz where n is the number of particles m^{-3} . f_p generally exceeds the electron cyclotron frequency but by typically less than an order of magnitude. In some regions off the equator, in particular a few Earth radii (R_e) above the auroral region ionosphere where much of the auroral kilometric radiation is believed to originate, the electron cyclotron frequency exceeds the plasma frequency.

This then sets the scene. The magnetosphere has hot and cold plasma populations, very largely collisionless and often far from thermodynamic equilibrium. Characteristic frequencies range from less than a Hz to hundreds of kHz (near the ionosphere). Waves are observed over the whole interval 1 mHz to about 1 MHz thus entirely containing the above range.

Waves around the electron cyclotron frequency

The word 'around' in the section title is to be interpreted loosely; the waves we look at in this section have frequencies from a few hundred Hz up to tens of kHz. We start by looking at frequencies below the electron cyclotron frequency. In a

cold plasma in this frequency range the wave that propagates is called the 'whistler' mode; the signal is in the acoustic band and recordings of signals which have come through the magnetosphere in this mode exhibit a characteristic whistling sound when played back through a tape recorder. Many whistler signals can be detected on the ground and some have an atmospheric source in lightning discharges.

It was recognised early on that whistler mode signals could strongly interact with energetic electrons⁴. These fast electrons see the wave signal doppler shifted to their cyclotron frequency and a resonant interaction results. Even small amplitude waves can produce large orbit perturbations. Most significantly the pitch of the resonant particle's helical orbit along the magnetic field is altered and in the presence of a spectrum of waves a nett 'pitch angle diffusion' results. Particles with smaller pitch angles mirror further down the flux tube closer to the Earth and thus have an increased chance of being lost by collision in the atmosphere.

In the interaction electrons lose energy to the whistlers as their pitch angle is reduced and as a result a distribution with a preponderance of particles with large pitch angles is unstable to whistler waves. Such a pitch angle (and pressure) anisotropy is produced naturally by convection. Kennel and Petschek⁵ pointed out that a steady state could be attained on a flux tube. Convection provided a source of particles while loss is by pitch angle diffusion. Waves gain energy because of the inherent instability but lose energy in bad ionospheric reflection. Development of a self-consistent theory still continues⁶.

In the magnetosphere it is interesting to note that two different kinds of whistler noise are commonly seen at high altitude. Outside the plasmasphere there is an emission called 'chorus'. Again named for its character, when replayed acoustically chorus resembles the dawn chorus of birds; the emission is sporadic, fluctuating on a time scale of seconds. Inside the plasmasphere the characteristic emission is a featureless 'plasmaspheric hiss' which effectively fills the high density region but is believed to be generated by cyclotron resonant interactions with >30 keV electrons near the outer edge⁷ of the plasmasphere. Detailed tests of the pitch angle diffusion theory have been made using typical wave fields and observed particle fluxes⁸ and it seems the basic mechanism is established. It is not established why chorus is structured in the way it is. The structure may well be allied to the nonlinear mechanism whereby signals from ground transmitters in the same frequency band generate sideband signals. Recently the Stanford group have shown that similar effects are achieved by very high harmonics of 60 Hz power line radiation entering the magnetosphere⁹ and have also shown that chorus occurrence may be related to power line radiation¹⁰.

An example of chorus and hiss occurrence is shown in Fig. 2 which shows data¹¹ from the Explorer 45 spacecraft. The spacecraft leaves the plasmasphere at 0424 UT (universal time). The hiss apparent in the channels below 1 kHz disappears at about this time and shortly afterwards chorus emissions appear in the 3.11 kHz channel for about an hour. It returns rather intermittently for about an hour before the re-entry of the spacecraft into the plasmasphere.

Also shown are emissions above the electron cyclotron frequency. In contrast to the whistler mode these signals have negligible magnetic signal and thus are electrostatic. First reported in 1970¹² these signals are specifically hot plasma phenomena which occur in bands between harmonics of the electron cyclotron frequency. They are regarded as responsible for pitch angle diffusion of the 1–10 keV electrons whose precipitation into the atmosphere provides the diffuse aurora. Simultaneous particle data from Explorer 45 (not shown) shows that the flux of these electrons is higher outside the plasmasphere than within it. The emissions are strongest in the band centred on $3f_p^-/2$. This is the characteristic band but near spacecraft apogee noise is present up to the $11f_p^-/2$ band. The theory of these waves and the associated precipitation is far short of the developed state of the whistler instability.

Fig. 2 Exp 45 (S³-A) spacecraft wave electric field data, orbit 214 day 23–23 January 1972. There are 15 narrow band channels and one broad band. Channel output is approximately proportional to the logarithm of the amplitude on a scale that varies from 2 $\mu\text{V m}^{-1}$ to 20 mV m^{-1} . Vertical lines are 64 s averages while dots indicate peak amplitudes in the same period. f_g and f_p indicate electron gyrofrequency and plasma frequency. PP marks exit from the plasmasphere. L indicates the radial distance of the equatorial point of the magnetic field line through the spacecraft (in R_E). UT is essentially Greenwich mean time and MLT is local time. MLAT is latitude with respect to the geomagnetic equator. From Anderson and Maeda¹¹.

It is more complicated than the whistler instability discussed above for a variety of reasons. Whistler waves are relatively fast and pressure effects are unimportant. Here they are all important and complicated because wavelengths are comparable to the mean Larmor radius of the electron population. It is now agreed that waves are driven by pitch angle anisotropy of electrons and also that a weak cold background plasma is important¹³ and it was shown that the growth rate should peak just below the upper hybrid frequency, $(f_p^2 + f_g^2)^{1/2}$ (refs 14 and 15). The fact that observation shows that the waves just above f_g^- seem to be preferentially excited is resolved by noting that the group velocity is smaller for lower frequency waves and thus they can stay longer in the generation region.

The waves are intense with amplitudes of 1–10 mV m^{-1} when compared with a background DC electric field associated with convection of a fraction of 1 mV m^{-1} in the magnetospheric equatorial plane and estimates¹⁶ suggest that their effect on particles they interact with are dramatic; 10 mV m^{-1} amplitudes are estimated adequate to provide pitch angle diffusion at a rate strong enough to fill the atmospheric loss cone in the time it takes a particle to move from one end of a flux tube to the other, the maximal 'strong diffusion' rate¹⁷. It is fair to say, however, that there is more theory and experiment to be done before we confidently understand the relationship between these waves and auroral precipitation.

One feature of Fig. 2 deserves further comment: also shown is a noise band labelled by f_p . This plasma frequency noise is expected from cold plasma theory and it corresponds to the electron population oscillating with respect to the more massive ions. The oscillatory motion is along the magnetic field and as expected this electrostatic noise is polarised in the direction of \mathbf{B} . Another noise band is reported throughout the magnetosphere at the upper hybrid resonance frequency. Again predicted by cold plasma theory this band expands to take in the hot plasma $(n + \frac{1}{2})f_g^-$ waves in the hot electron region outside the plasmasphere. As expected the UHR noise is polarised perpendicular to \mathbf{B} (ref. 18).

Ion waves

The right hand polarised whistler mode cuts off at the electron cyclotron frequency and in cold plasma theory there is a left hand polarised wave, the ion cyclotron wave, which cuts off at the proton cyclotron frequency. Energetic protons should be able to undergo gyroresonance with this wave mode in much the same way as electrons do with the whistler mode. Somewhat parallel theories were constructed⁵ and the decay of the ring current population in the recovery phase of a geomagnetic storm (a storm is a period when enhanced convection has shrunk the plasmasphere and increased the ring current population) is consistent with pitch angle diffusion loss induced by such waves¹⁹.

The waves are expected to occur at the high frequency end of the geomagnetic pulsation band (of which more later) and one type of emission in this band, called 'pearls', correlates with the recovery phase of storms²⁰. A second type of emission, intervals of pulsations with diminishing period (IPDP) is associated with substorms and has been identified simultaneously in space but without the decreasing period feature. This probably means

Fig. 3 Imp 6 spacecraft wave electric (lower panel) and magnetic field (middle panel) data in similar format to those in Fig. 2. The inset indicates the orbit in the late evening sector. The top panel shows background magnetic field strength and ϕ_{SM} is the azimuthal angle of the field in solar magnetospheric coordinates. For our purposes note that variations in ϕ are largely due to currents parallel to \mathbf{B} . λ_m is latitude with respect to the geomagnetic equator and R is radial distance from the Earth in R_E (Earth radii). From Gurnett and Frank²². Data are for 14 August 1971, day 226.

ground stations sample signals from a wider range of sources. Waves and particles have not been definitively correlated and some evidence that ion cyclotron waves are relatively infrequent²¹ may mean the instability is finely tuned. Theories agree that just inside the plasmopause is the place most conducive to instability and, as we have already mentioned, rather unusual proton distributions are produced there by steady convection. Ring current particles with energies below ~ 10 keV are absent and there is also a cut-off at high energy leaving particles with energies in a band ~ 10 –20 keV. If such distributions have developed the upper cut-off energy has a stabilising effect on wave growth while conversely the low energy hole in the distribution is destabilising. What is crucial is the contribution particles at upper and lower cut-offs make to the plasma pressure and this makes it feasible for such distributions to be stable to the waves.

The hole in the hot proton distribution predicted and observed at low energies would seem to be a good source of free energy for plasma waves but no correlation with waves has yet been reported. The distributions inevitably occur with the high density cold plasmasphere plasma as background and it is this cold background that inhibits the ion equivalent of the $(n + \frac{1}{2})f_g^-$ electrostatic waves discussed earlier.

Electrostatic ion waves above the ion cyclotron frequency are observed but outside the plasmasphere. Speculations on their existence had been made with the discovery of the electron waves¹² but discovery has been relatively recent²². These waves with frequencies from Hz up to kHz have peak power near 10–50 Hz and are found on flux tubes which map to auroral latitudes. The peak intensity is in the range of frequencies between the ion gyrofrequency and the lower hybrid frequency $(f_g + f_g^-)^{\frac{1}{2}}$ but extends up to f_g^- . These waves have amplitudes up to 10 mV m⁻¹.

At the upper end of the frequency range these waves are closely associated with an electromagnetic whistler mode emission called auroral hiss. Gurnett and Frank²³ report the hiss as extending outside the region of intense electrostatic signals which could indicate a common source, the electromagnetic signal being freer to propagate across the field. Downgoing hiss occurs in conjunction with intense 1–10 keV electron precipitation which in turn correlates with the discrete aurora structures and connections between this and the electrostatic waves remain an interesting source for speculation.

The signals occur over a wide range of local time and on the dayside the flux tubes containing the signals probably map to the polar cusp/magnetopause regions. The signals are found in the region where the higher latitude Birkeland currents flow and strong currents can be detected by the associated deflection of the Earth's magnetic field. Such deflections are seen within the electrostatic noise region and are associated with bursts of magnetic noise which seem to be propagating in the whistler mode but at a much lower frequency (~ 50 Hz) than the auroral hiss (kHz). Figure 3, taken from an outbound pass of the Imp 6 spacecraft on the nightside of Earth shows the electrostatic noise, auroral hiss and magnetic noise bursts²².

On the nightside the flux tubes on which the electrostatic noise occurs can reasonably be taken to map into the geomagnetic tail and it is appropriate next to mention that rather similar signals are seen in the tail regions^{23,24}. Figure 4 shows Imp 8 data 30 Earth radii down the tail near the midnight meridian. The noise is present and seen in much the same frequency bands as the noise seen much closer to Earth. Once again it is found in the regions where Birkeland currents occur, the outer edge of the plasma sheet whose signature is the depression in magnetic field seen in upper panel. The electric vector is at a large angle to **B**. Whistler mode noise bursts are also seen within the electrostatic noise region and it seems that the waves in the two regions are closely connected. One significant difference is that the far weaker tail magnetic field ($\sim 5\gamma$) means the signals are between the local lower hybrid frequency and the electron gyrofrequency, the frequency range occupied at low

altitudes by the auroral hiss.

In the tail these signals correlate with high proton flow velocities and with auroral kilometric radiation intensity, as Fig. 4 shows. In turn the auroral kilometric radiation which we discuss later is strongly correlated with auroral activity.

Theory to describe these waves is still in the early stages of development. Several years before the observations were made Kindel and Kennel²⁵ predicted instability of ion cyclotron waves in the topside ionosphere ($\sim 1,000$ km altitude). These waves are driven by a current of cold electrons from the ionosphere. In fact the waves are seen at considerably higher altitude ($> 2,000$ km) and extend to very large radial distances.

Although a current driven source is tempting an alternative energy source is anisotropic pitch angle distributions of hot protons and there are theories predicting ion electrostatic waves in the outer magnetosphere^{26,27}. Ashour-Abdalla and Thorne²⁷ point out that these waves are strongly damped by the collisionless Landau damping process if a background cold electron population is present. If these particles are carrying a current such damping can be suppressed and the mere appearance of these waves at night and day in regions where large Birkeland currents are expected and seen argues strongly in favour of current driven instability.

Fig. 4 Imp 8 spacecraft electric and magnetic wave data in format similar to that of Figs 2 and 3 from 30 R_E down the tail. The inset indicates the orbit in a plane perpendicular to the Earth-Sun line. When **B** is depressed the spacecraft is in the plasmasheet. θ_{SM} and ϕ_{SM} are solar magnetospheric latitude and longitude. Noise is seen in conjunction with gradients in **B**. Nothing significant appears near the indicated neutral sheet crossing. From Gurnett *et al.*²⁴. Data from day 281, 8 October 1974.

Kilometric radiation

Also shown in Fig. 4 in the highest frequency channels is a signal labelled auroral kilometric radiation. These are part of Earth's radio spectrum^{2,28} which extends up to 1 MHz in frequency. As mentioned earlier these waves make the Earth at times a radio source as bright as Jupiter and the existence of these waves raises interesting theoretical problems. Gurnett² estimates that the radiated power may be as much as 10^9 W which can be placed in context by noting this is of order of 1–10% of the energy deposition rate associated with the aurora. Determination of source location by lunar occultation using the lunar orbiter RAE2 has revealed that the radiation largely originates from auroral zone field lines with most coming from altitudes between 1–2 Earth radii²⁹. There is a second source at high altitude in the cusp. The radiation correlates with auroral activity³⁰ and the flux changes by three orders of magnitude between quiet and disturbed times³¹.

These waves make a fascinating theoretical problem. There is no doubt they are in some way tapping energy available in auroral primary particles. Most theorists would agree on two points. The process is efficient ($\leq 10\%$ of auroral energy is converted into waves) and also the generation process is indirect in the sense I shall now describe. Radio waves propagate faster than light and thus it is argued cannot directly interact with a beam of auroral electrons. Rather a beam might be expected to generate electrostatic noise which then generates or is converted into the electromagnetic radio waves. Kaiser and Alexander³¹ show source frequencies are of order of the local upper hybrid and electron cyclotron frequencies and it is not unreasonable for a beam to generate electrostatic noise at such frequencies. Some theories³² then postulate conversion of the wave into a radio wave because of plasma inhomogeneity, conversion occurring when the wave frequency is near the local plasma frequency. An alternative theory³³ relies on large amplitude turbulence at the upper hybrid frequency to generate radio wave energy at twice the UHR frequency by nonlinear conversion. An ingenious idea of Palmadesso *et al.*³⁴ has a high frequency electrostatic wave generated by the beam interacting with a short wavelength low frequency ion wave to provide a high frequency long wavelength radio wave by wave-wave interaction.

All these theories have some disadvantages. On the basis of propagation cut-offs it is thought the waves are right hand polarised³⁵; the Palmadesso *et al.* theory predicts left hand polarisation. Very large amplitude electrostatic waves are required for nonlinear conversion while steep gradients are required for the most efficient conversion by inhomogeneity. There is so far little evidence of intense electrostatic noise in the appropriate frequency range though it can be argued that peculiarities of orbit coverage have left some of the expected source region relatively unexplored.

One alternative remains. It is possible for particles to see a radio wave doppler shifted to their cyclotron frequency and experience a direct gyroresonance interaction with the wave in this manner. This approach has been adopted by Melrose³⁶ who suggests the same mechanism may explain the similar radiation from Jupiter in the decametric band. Because the beam-wave interaction can be direct rather than a two-stage process it is appealing. The difficulty is that very extreme particle distributions appear to be needed if the electrons are to achieve a nett transfer of energy into the wave in the interaction.

The final story cannot then be said to be established. It will certainly involve the beams of electrons that are observed above the discrete aurora, the precise way the electrons in them are distributed in energy and pitch angle and probably also their distribution in space along with knowledge of the cold plasma distribution. It will also need to recognise the lower frequency hiss and ion waves that seem to originate in a similar vicinity. We discuss some further features of this region in the next section.

There is a second class of signal in the kilometric band as yet not definitely explained²⁸. This is the continuum radiation of much lower intensity and far more regular in character. Circumstantial evidence links this radiation with the plasma sheet electrons outside the plasmasphere and perhaps with the $3f_g/2$ electrostatic waves.

Anomalous resistivity

Anomalous resistivity remains a topic of great interest in the magnetosphere. There is circumstantial evidence of its occurrence, but much of the story waits to be developed. To understand what it is and its role, it is important to note that in a collisionless plasma one would expect the electrical conductivity along the magnetic field to be effectively infinite. The magnetospheric convection system requires currents to flow parallel to **B** as outlined earlier, though with more detailed structure expected on flux tubes that map to the neutral sheet region³⁷. Because of the high conductivity very small electric fields are required to give cold electrons a drift adequate to provide the requisite current. Once the current exceeds a threshold value, however, instability can set in. Energy from the drift motion is given up to plasma waves travelling at a similar speed to the current carrying particles. Naturally an increase in parallel electric field is then required to maintain the current. The effect of the instability is thus to increase the resistivity of the plasma.

In the presence of a turbulent wave spectrum the process is somewhat akin to the pitch angle diffusion process described earlier. Particles resonate with waves with phase speeds equal to their speed along **B** and the result of this strong interaction is that energy is fed to the wave while the particle diffuses in velocity. This process replaces the rôle of collisions in classical conductivity. If waves become strongly nonlinear the situation becomes far more complicated, wave-wave interactions may need to be considered and the radiation pressure of the waves can become important. Spatial structure is then produced by the exclusion of particles from regions where signals are most intense. Determining what stabilises a given turbulence spectrum is a taxing theoretical problem³⁸ but in the magnetosphere one test is to take an observed spectrum of waves and compute the particle scattering by the spectrum without considering the stabilisation problem. In fact given a wave spectrum regardless of the precise underlying instability one finds the effective collision frequency, ν^* , introduced by the turbulence is roughly given by

$$\nu^*/2\pi f_p \sim \epsilon_0 \langle E^2 \rangle / 2p$$

That is, the ratio of effective collision frequency to plasma frequency is of order of the ratio of the wave energy and electron pressure. Such a formula was used by Fredericks *et al.*³⁹ in a detailed study of a double sheet of current found in the polar cusp region. Wave field strengths of 90 mV m^{-1} in a frequency band stretching from below 560 Hz up to several kHz were estimated to provide an anomalous resistivity 7.9 ohm m . Using the estimate of the current density deduced from spacecraft magnetometer measurements they estimate there existed a potential drop along the magnetic field of about 2 kV, enough to provide significant auroral acceleration and precipitation.

As the effective collision rate is proportional to the square of the turbulent wave amplitude and the amplitudes reported by the Iowa group near the Earth²² and in the tail²¹ are at most a few tens of mV m^{-1} and a few mV m^{-1} respectively, resistivity due to the electrostatic turbulence emphasised in this paper is generally substantially lower. Gurnett and Frank²² suspect that in a region on appropriate flux tubes at about 1.8–4 Earth radii radial distance, as yet large unexplored, amplitudes would be higher. Some earlier reports suggest this is so⁴⁰.

Much interest centres on anomalous resistivity because of the uncertain role of parallel electric fields in acceleration of auroral

particles. In circumstances where a current of low energy particles is being disrupted, energetic particles can form a beam by running away in the parallel electric field³⁸. As mentioned earlier beams are seen in association with the low frequency noise. A recent observation⁴¹ in fact shows the noise in the presence of d.c. electric field structures suggesting a strong parallel field is present at the same time.

It is by no means a foregone conclusion that strong parallel electric fields are the prime auroral acceleration process. In fact at times the flux of energetic auroral primaries seems capable of carrying the observed Birkeland current. Causal relationships have still to be worked out in detail and another region where rapid particle acceleration is expected is the tail neutral sheet where, as briefly mentioned earlier, field lines undergo reconnection. Strong currents across the magnetic field are involved in this and one can picture the process as a conversion of magnetic energy into particle energy, but the proportions that go into thermal motions against directed motions (flows and beams) is not firmly established and probably variable. Observational information on flows in the tail is still a relatively recent development. Theories divide into quiet and turbulent current flow models. It does seem that macroscopically the flow is turbulent where the magnetic field is weak⁴² but there is a lack of any evidence of strong high frequency turbulence associated with current sheets. The only report⁴³ is of electrostatic waves of the $3f_e/2$ type with low amplitude ($\sim 300 \mu\text{V m}^{-1}$ peak intensity). This could mean beam formation could occur in the neutral sheet region without much disruption.

Hydromagnetic waves

The phenomena discussed in this section are rather a contrast to those in the immediately preceding sections. Hydromagnetic waves are the lowest-frequency waves that are seen in the magnetosphere and a large number of them can be detected on the ground as geomagnetic pulsations, small fluctuations in the Earth's magnetic field. Their frequency is much below the proton cyclotron frequency and to a first approximation protons and electrons move together in the wave, the collisionless plasma behaving much like a fluid. One result of this is that waves can be described in hydrodynamic terms as well as electromagnetic. As with the background flow described earlier, the flux tube or field lines can be thought of as frozen into the wave flow and through the Maxwell stress tensor one can picture the forces which the magnetic field exerts on the plasma as a tension B^2/μ_0 along the field direction plus an isotropic pressure $B^2/2\mu_0$. A result of this approach is that one hydromagnetic wave mode can be recognised as directly analogous with waves on a stretched string. This mode, the Alfvén mode, has a magnetic perturbation perpendicular to \mathbf{B} , and thus bends the field without changing the magnetic pressure. These waves move along \mathbf{B} at the Alfvén velocity $B/(\mu_0\rho)^{1/2}$, (ρ is mass density). The equatorial Alfvén velocity is of order 10^2 – 10^3 km s^{-1} in the magnetosphere while pulsation periods range from seconds up to ten minutes. One expects wavelengths comparable to the length of the field line (from ionosphere to ionosphere) for many of the signals seen and if this is so standing wave structures form along the field lines. As neither \mathbf{B} nor ρ are uniform each field line (or more specifically field shell) has its own set of resonant frequencies. Such field line resonance signals eventually damp if only because the ionosphere does not perfectly reflect waves and the fact that the dayside ionosphere should reflect better than the nightside fits well with the observed morphology that continuous pulsations are more common by day and irregular damped pulsations more common at night⁴². However, other sinks of energy can be important including collisionless damping and also dayside and nightside energy sources do differ.

The best experimentally documented theory of dayside pulsation origin is that broadband hydromagnetic turbulence is set up near the magnetospheric boundary by the Kelvin-Helmholtz (wind-over-water) instability. The magnetosphere

then acts like a filter in that energy at a particular frequency is selectively amplified on the flux tubes that resonate at that frequency^{44,45}. The most recent evidence in favour of this source comes from magnetic field measurements made on three geosynchronous spacecraft, SMS1, SMS2, and ATS6 (ref. 46). This study showed that most signals show tailward-phase motion across the background field both in the morning and the afternoon, exactly as one would expect for waves driven by the solar wind. Some of the results are shown in Fig. 5. What is shown is the East-West angular wave number. There is a distinct tendency for the wave propagation sense to switch near local noon—best evident in the low frequency band.

Now the Hughes *et al.* study⁴⁶ is also important in showing the existence of a separate class of waves with short wavelengths across the background field. In Fig. 5 there is a gap in the data in the late afternoon (21–24 UT). Power was still present at this time of day but the signals showed little coherence between spacecraft, and thus phase difference measurement was not possible. One concludes that these signals have wavelengths shorter than the 4° longitude spacing of the geostationary spacecraft. Short wavelengths across the field are a characteristic of driftwaves, low frequency waves that occur in inhomogeneous plasmas, and these have received much attention in studies of laboratory plasma⁴⁷. Such waves are driven by extracting plasma internal energy where pressure

Fig. 5 The angular wave number perpendicular to the background magnetic field of hydromagnetic wave signals seen on two geostationary spacecraft ATS6 and SMS2. Positive wave number indicates eastward propagation and the change in sense near local midday indicates waves that are solar wind driven. The gap in the data in late local afternoon is significant and is discussed in the text. Dots and crosses distinguish polarisation differences not discussed here. From Hughes *et al.*⁴⁶.

gradients are present. There is little experimental evidence of the purely electrostatic modes that have received most attention in the laboratory context. Although measurement *in situ* of electric field is difficult at these frequencies such modes would cause particle flux oscillations and thus be detected. Electric field amplitudes of magnetic pulsation signals have been deduced in this way⁴⁸ directly confirming the standing wave structure described earlier. Back-to-back energetic proton detectors have detected wave variations on the scale of a Larmor radius⁴⁹. The particles involved in these observations are in the energetic tail of the distribution and as yet there has been no evidence that wavelengths across the field are as short as the thermal Larmor radius.

Hydromagnetic wave research can also be done on Earth relatively cheaply. Much of the field line resonance picture outlined above was developed in the light of data recorded on meridian chains of magnetometer stations on the ground. Curiously enough, measurements of East-West phase have been done only recently. Studies of waves using the British Institute of Geological Sciences magnetometer network at latitudes corresponding to inner magnetosphere flux tubes showed that their wavelengths were too long ($\sim 60^\circ$ of longitude) to be of drift wave origin while their propagation direction, preferentially eastward all day, was inconsistent with Kelvin-Helmholtz generation⁵⁰. In contrast recent high latitude measurements (Olson and Rostoker, personal communication) have shown consistency with the Kelvin-Helmholtz source like the geosynchronous spacecraft data.

Many pulsations may be driven by fluctuations in background convection and one class almost certainly is. These are the nightside 'pi 2' signals which at times can look like a text-book damped sine wave. An example of a train of such waves is shown in Fig. 6⁵¹. The upper trace was recorded near midnight in Newfoundland and shows a series of pi 2s while the lower trace was recorded in Lerwick, in the Shetlands, in the early morning. The more continuous Shetland pulsations show enhancements with the pi 2 bursts at midnight⁵¹. The midnight sector is where the most abrupt changes associated with substorms are seen. Pi 2 signals appear in close relation to the auroral intensifications, changes in convection and magnetospheric configuration. This was first pointed out ten years ago⁵² and one school now regards them as providing the best timing scheme for substorms⁵³. It seems reasonable to regard them as transients of the system associated with field lines coming to a new equilibrium with a change in convection conditions, like the twanging of telegraph wires in a gusty wind, and it would in fact be surprising if such did not occur. Their potential diagnostic use, however, is that they can appear outside the region where the most dramatic occurrences are. This is but one example of a plasma wave as a magnetospheric diagnostic. Other examples are legion and we could explore the subject much further.

Concluding remarks

This survey has not been exhaustive, but was designed to be illustrative of the type of knowledge we have. Instances of omissions are any mention of the magnetosheath, bow shock and near-Earth solar wind which closely relate to the magnetosphere and which each contain their own characteristic plasma waves known in a similar manner to those of the regions interior to the magnetosphere. We are also aware that magnetospheres other than Earth's have their own wave phenomena, with Jovian radio emissions being a prime example. Direct measurements of plasma waves within the Jovian magnetosphere have yet to be made but no doubt will be. Moving to a cosmic scale both solar and pulsar radio phenomena have been suggested to have origins similar to terrestrial radiation. In the Earth's magnetosphere we have the unparalleled advantage of direct sampling of the plasma in which the radiation originates, and of knowing the trapped plasma wave spectrum as well. Thus far these advantages have led to success-

Fig. 6 Examples of nightside pulsation activity. Local time at Lerwick (b) is close to UT. St Anthony is $3\frac{1}{2}$ h behind and is near midnight. pi 2's at St Anthony (a) show as enhancements of low-level continuous activity at Lerwick. From Stuart and Booth⁵¹. Data from 21 August 1972.

ful developments of explanative collisionless plasma theory. One should also note that one often has more information about the plasma than in a laboratory plasma. Certainly the parameters a theorist wants to know (for example particle distribution in energy) are often very close to what is measured. There are, however, tantalising areas of exploration left. Often spacecraft have not flown with the right combination of instruments. International Magnetospheric Survey (IMS) activities on the ground and in space now underway should be productive. Worth a particular mention are the GEOS spacecraft of ESA and the NASA/ESA joint ISEE spacecraft projects. Both are well equipped to study waves and the latter is a multiple spacecraft project and as such the first of its kind. Happily, in the field of plasma waves alone there still remain many questions for them to answer.

Limits to the expansion of Earth, Moon, Mars and Mercury and to changes in the gravitational constant

M. W. McElhinny, S. R. Taylor & D. J. Stevenson

Research School of Earth Sciences, Australian National University, Canberra, A.C.T., Australia

New estimates of the palaeoradius of the Earth for the past 400 Myr from palaeomagnetic data limit possible expansion to less than 0.8%, sufficient to exclude any current theory of Earth expansion. The lunar surface has remained static for 4,000 Myr with possible expansion limited to 0.06%, the martian surface suggests a small possible expansion of 0.6% while the surface of Mercury supports a small contraction. Observations of Mercury, together with reasonable assumptions about its internal structure, indicate that G decreases at a rate of less than $8 \times 10^{-12} \text{ yr}^{-1}$, in constant mass cosmologies, and $2.5 \times 10^{-11} \text{ yr}^{-1}$ in Dirac's multiplicative creation cosmology.

THE proposition that the Earth has expanded through geological time has received new impetus from those who claim that plate tectonics do not adequately account for many aspects of geology¹⁻³. It has been proposed that seafloor spreading exceeded subduction by 33% during the past 165 Myr, corresponding to an expansion of the Earth of over 10% since the Jurassic⁴. The possibility that the Earth or any of the planets have expanded has profound implications in cosmological theory because such expansion is predicted by models that suppose that the gravitational constant G has been decreasing with time⁵⁻⁸. It is not possible to calculate any possible changes in the Earth's radius from an examination of its surface features because these have been continually reshaped by a variety of geological processes. The only viable technique is that which uses the results of palaeomagnetic studies. In the past the number, reliability and lack of coverage of the Earth's surface of these measurements has made it difficult to make palaeoradius calculations with any accuracy. Successive analyses, however, have tended to eliminate all but the slowest ($< 2.5 \text{ mm yr}^{-1}$) expansion rates⁹. The situation has improved so much over the past decade that estimates can now, in favourable situations, be made with an accuracy of a few per cent. On the other hand, the results of the lunar exploration programme have shown that the surface of the Moon has remained relatively unchanged for nearly 4,000 Myr. Observations of the surface of Mercury and Mars by spacecraft enable constraints to be placed on the palaeoradius of these extraterrestrial bodies. Here we shall analyse palaeomagnetic data to provide constraints on the past changes in the Earth's radius and then look at the available data for the Moon, Mars and Mercury to limit possible changes that could have occurred in these bodies.

Palaeoradius of the Earth

Egyed^{10,11} first pointed out that palaeomagnetic data could be used to calculate the Earth's palaeoradius for different geological epochs. He showed¹⁰ that if two widely separated palaeomagnetic sampling sites were available for the same geological period and situated on the same palaeomeridian, the past latitude separation could be calculated from the observed palaeomagnetic inclination at each site. The ratio of the present angular separation to the past angular separation (determined by the palaeolatitude difference) was then the ratio of the past to present radius. Generally, of course, sampling sites are rarely on the same palaeomeridian and Egyed later suggested a more general triangulation method¹¹ that allows sampling sites to be arbitrarily located. Van Hiltten¹² first used this method in a much modified form and concluded that a substantial increase in the Earth's radius had occurred since the Permian. A closer analysis¹³ of Van Hiltten's method, however, has shown that his technique is incorrect and produces results that are at variance with his model. Van Andel and Hospers¹⁴ later proposed an improved triangulation technique and subsequently reviewed all estimates of the Earth's palaeoradius⁹ concluding that hypotheses involving large expansion rates^{15,16} could be rejected.

Ward^{17,18} has proposed a method which is appropriate to the spherical environment of the palaeomagnetic data. The analysis uses all data from a continental block in a single calculation. The dispersion of palaeomagnetic poles is investigated using Fisher's¹⁹ analysis of dispersion on a sphere for different values of Earth radii. That radius for which the dispersion of poles is a minimum is regarded as the best estimate of the palaeoradius for that data set. All results up to the end of 1976 and which conform with the minimum criteria for reliability set out by McElhinny²⁰ have been analysed in a new global review of palaeomagnetic data. The basic data set consists of the coordinates (λ_m, ϕ_m) of n rock units each having palaeodeclination and inclination (D_m, I_m). The Fisher¹⁹ mean position (λ_0, ϕ_0) of all rock units is calculated and the basic data are transformed to a new coordinate system with (λ_0, ϕ_0) as the pole to yield new values ($\lambda'_m, \phi'_m, D_m, I_m$) in this system. In this coordinate system, as the radius of the earth is changed (the continent keeping the same physical dimensions) so the latitude of the rock units (λ'_m) will change to some new value (λ''_m) but the longitudes (ϕ'_m) will be unchanged. For each value of radius new values λ''_m may be calculated and the resulting dispersion of the palaeomagnetic poles determined.

Table 1 lists calculations for several continents for those

Table 1 Estimates (R_a) of the Earth's palaeoradius as a fraction of its present radius

Block	Age	N	D_{\max}	K_{\max}	Data centre	Fixed centre	R_d	R_f	R_a

R_a using palaeomagnetic data and Ward,^{17,18} method. R_d is the estimate using the average site location (data centre) as the pole for the coordinate system used in the calculations and R_f is the estimate using the approximate centre of the continental block as pole. N is the number of palaeomagnetic results used, D_{\max} is the largest great circle distance (in degrees) between any two palaeomagnetic locations and K_{\max} is the maximum value of Fisher's¹⁹ precision parameter for the palaeomagnetic poles. * No solution is possible.

Continental combinations use standard reconstructions^{22,23}. The values in brackets include data used in the larger set immediately following in each case. Calculations have only been listed where 10 or more locations are available.

geological periods where the palaeomagnetic results number 10 or more. One criticism of Ward's method is that the mean position of the rock units investigated is taken as the point at which strain due to curvature changes is zero. This might be far removed from the actual central point of the continent. The calculations have in each case been repeated using an approximate fixed central point in each continent. The differences between R_d (data centre) and R_f (fixed centre) calculations are negligible. So as to be unbiased, the mean, R_a , of these two values is taken as the best estimate in each case. In some instances Ward's method gives no solution because the data have been collected from too small a region of the continent. In many instances the change of the Fisher precision parameter K with radius is small and the solution for the ancient radius is not well determined. The best solutions in Table 1 are those in which there is the largest distance between the most widely separated rock units coupled with the largest number of observations. Even so the best of these determinations, probably from the Triassic–Jurassic of Africa, is only accurate to about 10% (ref. 21).

The data of Table 1 exhibit no systematic variation of radius with time from Devonian through to the present. The average radius over the past 400 Myr expressed as a function of the present radius is calculated as 1.01 ± 0.03 at the 95% confidence level taking the mean of the 14 independent estimates listed in Table 1. We can, however, improve the accuracy of the individual determinations by combining the data into larger sets, such as combining the data for Europe and Asia in post-Permian times or else reconstructing the continents into larger blocks that are known to have existed in the past. The first six entries of Table 2 involve a reconstruction of the Atlantic²² (Europe–North Amer-

ica, or Africa–South America) about which there is little dispute. Each of the six entries involves more than 25 rock units with a spread of at least 6,000 km between the most distant ones. The accuracy of each of these estimates of palaeoradius is probably about 5% at the 95% confidence level. The lower half of Table 2 gives calculations based on the Smith and Hallam²³ reconstruction of Gondwanaland and for the Triassic–Jurassic combining also with North America²². The accuracy associated with these calculations depends on one's view of the precision of the reconstruction used.

The first six entries of Table 2 provide the best overall estimates of the palaeoradius from all the palaeomagnetic data. Figures 1 and 2 illustrate the solutions for the presently largest single block (Eurasia) and for a reconstructed block (Africa–South America). Once again the results indicate no systematic change of radius with time since the Devonian. For the past 400 Myr the average palaeoradius may be calculated as 1.020 ± 0.028 (95% confidence limits). This value suggests a slight contraction of the Earth rather than an expansion. Any expansion is limited to less than 0.8% in 400 Myr. This corresponds to a maximum possible expansion rate of 0.13 mm yr^{-1} , a value sufficiently small not only to exclude the fast expansion of rates proposed by Carey^{2,15} and Hilgenberg¹⁶, but also to exclude the much slower rates proposed by Egged²⁴ (1 mm yr^{-1}) or Wesson²⁵ (0.6 mm yr^{-1}). The data are marginally consistent with the contracting Earth models of Lyttleton⁵⁰, but the phase-change hypothesis in Lyttleton's theory is inconsistent with present knowledge of the equation of state of dense matter⁵¹, and the enormous latent heat required (equivalent to a temperature drop of 10,000K) was incorrectly omitted in his thermal evolution calculations.

Moon, Mars and Mercury

The surface of the Earth is not an ideal location in which to seek evidence of expansion. Although the geological record extends to 3,700 Myr, plate tectonic activity in the past 200 Myr is chiefly responsible for the presently observed surface structures. The inherent difficulties in interpreting the geological record are well known, and it is salutary to recall that the fleeting nature of the present landscape became an accepted fact less than 150 yr ago^{26,27} while the dynamic processes of recent seafloor spreading and continental movement became established only within the past 15 yr.

In contrast, the surface of the moon has remained apparently static for more than 3,000 Myr. Telescopic and orbital mapping, aided by manned lunar landings have established the essential features of the lunar surface^{28,29}. The terrain is divisible into two major areas, the maria and the highlands. The latter form an older heavily cratered surface. The origin of the large craters by meteoritic or asteroidal impact is now established. Evidence for the bombardment of the lunar surface by larger (~50 km diameter) objects is provided by the recognition of over 40 large (>220 km diameter) ringed basins, saturating the highland surface. Similar basins occur on Mercury³⁰ (for example, Caloris basin) and Mars³¹ (for example, Hellas, Argyre). Following the excavation of the basins, basaltic lavas flooded 17% of the lunar surface³². Since then, the only visible changes have been the production of younger impact craters (such as Tycho, Copernicus, Kepler) of which 15 are visible telescopically on the Earth-facing side.

A significant achievement of the Apollo Programme was the establishment of the absolute age of these events. This knowledge, obtainable only from the returned rock samples collected by the

astronauts, constitutes a major scientific justification for the manned lunar landings. The highland crust formed before 4,400 Myr and was subjected to a massive bombardment which terminated at 3,900 Myr (refs 33–35). The basalt lavas, generated by partial melting deep (100–400 km) in the lunar interior, poured across the highland surface for at least 700 Myr, beginning at or just before the termination of the bombardment of the highland crust (3,900 Myr) and continuing to at least 3,200 Myr (ref. 29). Possibly some late flows continued to about 2,600 Myr (ref. 32). The surface has remained essentially static since 3,200 Myr. Most of the geological record preserved on the Earth postdates these events. There is no evidence of large-scale expansion or contraction³⁶ or any displacements resembling those produced by plate motions on the Earth.

Some minor features of lunar topography call for comment. In the highlands, some alteration of crater shapes has occurred. Such occasional distortions are attributable to the degradation of craters during subsequent cratering or basin-forming events³⁷. These massive events transport debris widely across the lunar surface, with extensive formation of secondary craters³⁸, and crater chains. Many effects previously attributed to volcanic or tectonic activity on the lunar surface are now explained by this mechanism^{37,38}. These basin-forming events terminated at 3,900 Myr (ref. 33). Faint lineations, referred to as the 'lunar grid'³⁹ have been detected by some workers. These may represent a faint residual trace of an early crustal cooling history. The 'grid', however, may result principally from the overlapping of outthrown debris produced by the giant basin forming collisions. In any event, it was produced before 3,900 Myr.

On the mare surfaces, wrinkle ridges³⁶, concentrated around

Fig. 2 Calculation of the palaeoradius for late Permian to early Jurassic data from Africa and South America after reconstruction of the South Atlantic according to the fit of Bullard *et al.*²² *a*, Permo-Jurassic; *b*, Triassic-Jurassic. The variation of the Fisher¹⁹ precision parameter for the palaeomagnetic poles as a function of radius (past/present) is shown below the locality map (●, Triassic-Jurassic localities; ▲, Permo-Triassic localities).

Fig. 3 Mariner 10 photograph of the northern limb of Mercury, showing a prominent east facing scarp, extending from the limb near the centre of the photograph, southwards for hundreds of kilometers. The linear dimension along the bottom of the photograph is 580 km. The picture was taken at a distance of 77,800 km from Mercury. (NASA Photograph P. 75-61-JPL-654-5-75).

the rims of the circular maria, seem to be due to localised cooling and draping of the lava sheets over pre-existing ridges. Occasional small grabens (straight rilles) in the maria are attributable to local cooling and shrinkage. Radial and concentric fractures in some basalt-filled craters²⁸ (for example, Gassendi, Humboldt) are apparently due to the same cause. The lack of present moonquake activity associated with these features is additional evidence for their antiquity. The most impressive features of the mare surface on a global scale are their smoothness (attributable to the low viscosity of the iron-rich lunar lavas) and the absence of evidence of tectonic movement since solidification.

The surface of the moon thus seems to have been frozen in its present form since about 3,200 Myr. It is possible to extrapolate this to 3,900 Myr when the last major structural events (formation of the Imbrium and Orientale ringed basins) occurred³³.

In contrast to the Moon, Mars shows evidence of slight expansion^{31,36,41}. Estimates of the chronology of the complex geological history discernible on Mars are not well established, being dependent on crater flux estimates and analogies with events on the moon^{42,43}. An early heavy bombardment produced the cratered terrain, still preserved in the southern hemisphere³¹. The next significant event seems to be the commencement of the uplift of the Tharsis region. This continent-size plateau is now about 6,000 km across and up to 10 km high. Radial fracturing of the martian crust accompanied this uplift. The next stage was the widespread production of volcanic plains, covering most of the northern hemisphere. A second stage of the Tharsis uplift now occurred, with further radial fracturing and the formation of large troughs. Finally the build-up of the large volcanic edifices (such as Olympus Mons) took place.

The dating of these events is difficult due to uncertainties in the crater flux rates. Present views^{42,43} date the old cratered terrain at about 4,000 Myr or older, from analogy with the lunar highlands.

The final uplift of the Tharsis plateau occurred about 1 Myr ago, and the large volcanoes are perhaps 200 Myr old^{42,43}. The Tharsis uplift thus seems to have occurred between about 4,000 and 1,000 Myr ago.

No major tensional features are observable on Mercury⁴³⁻⁴⁵. Extensive lobate scarps (Fig. 3) (20–500 km long and from 0.2–3 km high) provide evidence of contraction, with an upper limit of about 2 km since the formation of the crust. This effect is attributed to the contraction of a 600 km thick silicate shell around a cooling iron core⁴⁵. These scarps clearly formed later than the crust itself. From the observable crosscutting relationships, the formation of the scarps occurred close to the end of the period of major bombardment of the Mercurian surface, extending possibly a little beyond the stage^{44,45}. By analogy with the lunar highland surface, which the Mercurian landscape greatly resembles⁴⁴, the age of the heavily cratered surface is at least 4,000 Myr.

Table 3 provides estimates of the maximum change in planetary radii. For the moon, the expansion or contraction since 3,900 Myr is $< \pm 1$ km. For Mercury, a contraction of about 2 km has occurred probably before about 4,000 Myr (ref. 46). Since then, there is no evidence to support any further contraction or expansion. We therefore place limits of ± 1 km for the change in radius of Mercury over the past 3,000 to 4,000 Myr.

For Mars, the problem is more complex. The Tharsis Plateau is here assumed to be an uplifted feature due ultimately to thermal expansion^{31,36}, the case most favourable for variable G hypotheses. An alternative that it is a residual bulge following planetary contraction is less obviously reconcilable with the geomorphic evidence³¹. The maximum expansion has been estimated from thermal model calculations³⁶ to be about 19 km between 4,600 and 1,000 Myr. There seems to be no evidence for any expansion over the past 1,000 Myr. In Table 3, we give two estimates of the possible change in martian radius. Mars Model A assumes a 19 km expansion over 3,600 Myr, corresponding to the earlier martian record. Mars B assumes a possible ± 1 km change in radius during the past 1,000 Myr.

Variation of gravitational constant

Cosmologists have generally accepted the view that distant matter in the universe spherically distributed about the Earth has no noticeable effect on the Solar System. As the Universe expands and distant matter moves away from us it is supposed that there are no locally induced consequences. Exceptions to this view have been propounded by Dirac⁵, Jordan⁶, Brans and Dicke⁷, and Hoyle and Narlikar⁸. Jordan⁴⁷ later adopted a new cosmology closely paralleling that of Brans and Dicke. If the expanding Universe results in changing effects on distant matter, the consequences are a steadily decreasing gravitational constant. The Brans–Dicke theory of gravitation proposes a decrease in G of about $1 \times 10^{-11} \text{ yr}^{-1}$, for $\omega = 6$, where ω is the scalar coupling constant⁴⁸. But, recent lunar laser ranging data⁴⁹ require $\omega > 29$, and this limits the decrease in G to about $2 \times 10^{-12} \text{ yr}^{-1}$ for this theory.

In contrast, the theories of Dirac⁵² and Hoyle and Narlikar⁸ predict decreases of about $5 \times 10^{-11} \text{ yr}^{-1}$, when G is measured in atomic units. In Dirac's theory, there is also continuous creation of matter, and Dirac proposed two possibilities: additive creation and multiplicative creation⁵². In additive creation, matter is

Table 3 Palaeoradii (R_a) given as a function of present radius for the Earth, Moon, Mars and Mercury

Planet	R_a	α	Time (10^9 yr)	Constant mass	$-\delta G/\text{Gyr}^{-1}$	Multiplicative creation
Earth	1.020 ± 0.028	0.085 ± 0.02	0.4	$\leq 3 \times 10^{-10}$		$\leq 5 \times 10^{-9}$
Moon	1.0000 ± 0.0006	0.0004 ± 0.001	3.9	$\leq 5 \times 10^{-11}$		$\leq 1.5 \times 10^{-10}$
Mars A	0.9944	0.03 ± 0.01	3.6	$\leq 8 \times 10^{-11}$		—
Mars B	1.0000 ± 0.0003	0.03 ± 0.01	1.0	$\leq 1.5 \times 10^{-11}$		$\leq 4.5 \times 10^{-11}$
Mercury	1.0000 ± 0.0004	0.02 ± 0.005	3.5	$\leq 8 \times 10^{-12}$		$\leq 2.5 \times 10^{-11}$

The theoretical parameter α (see equation (3)) is listed and the corresponding maximum limits to the rate of decrease of the gravitational constant G are indicated. The models corresponding to Mars A and B are explained in the text.

created uniformly throughout the Universe and only the variation of G affects the planetary structure. In multiplicative creation, matter is created locally in proportion to the matter already present. In this case, the mass of a planet M increases at twice the rate as G decreases.

If the planet is in hydrostatic equilibrium then the pressure P at radius r within the planet satisfies

$$\frac{dP}{dr} = -\frac{G\rho(r)M(r)}{r^2} \quad (1)$$

where $M(r)$ is the mass within radius r . This can be rewritten as

$$\frac{dP}{dr^*} = -GM^{2/3}\frac{\rho(r^*)M^*(r^*)}{r^{*2}} \quad (2)$$

where $r^* \equiv r/M^{1/3}$, $M^*(r^*) = M(r)/M$. It follows that $R^* \equiv R/M^{1/3}$, where R is the radius of the planet, is a function only of $GM^{2/3}$ and the equation of state $P(\rho)$. A homologous change ($R \propto M^{1/3}$) would not be detectable in the observations we consider, since it scales all linear dimensions equally, so only variations in R^* need to be considered. In Dirac's Multiplicative Creation (DMC), $G \propto t^{-1}$ and $M \propto t^2$, where t is the elapsed atomic time, so $GM^{2/3} \propto t^{1/3} \propto G^{-1/3}$. It follows that for our considerations, DMC is exactly equivalent to a constant-mass theory in which G increases at one third of its actual rate of decrease. We can, therefore, restrict the following analysis to constant M .

The variation of R as G changes can be parameterised as

$$\frac{1}{R} \frac{dR}{dt} = -\frac{\alpha}{G} \frac{dG}{dt} \quad (3)$$

where α is to be calculated as a function of G and M . For a given $P(\rho)$ and the boundary condition $P(r=R)=0$, the solution of equation (1) for different values of G enables one to calculate α . For the particularly simple case of a polytropic gas, $P = C\rho^n$, dimensional considerations alone demonstrate that $\alpha = 1/(3n-4)$, independent of G and M . This result was applied by Hoyle and Narlikar⁵³ to the Earth, and by Crossley and Stevens⁵⁴ to Mercury, but neither application is valid as $\rho = 0$ at $P = 0$ in a polytropic gas, whereas the surface density of the terrestrial planets is finite. Because the value of α for small planets is required, it is more appropriate to derive a theory for the limit of small gravitational self-compression. This is certainly valid for the Moon, Mercury and Mars; and can be extended to include the Earth. Neglecting phase transitions and chemical layering for the moment, it is sufficient in this limit to set $P = K_0(\rho - \rho_0)/\rho_0$ in equation (1), where ρ_0 and K_0 are the zero-pressure density and incompressibility. Solution of equation (1) to lowest nonvanishing order in G is then:

$$\rho = \rho_0[1 + (\Delta\rho/\rho_0)(1 - r^2/R^2)]$$

$$\Delta\rho/\rho_0 \equiv 2\pi G\rho_0^2 R^2/3K_0 \quad (4)$$

The total mass M can be evaluated. The requirement that M be constant, as G and R change, gives

$$\alpha = \frac{2}{15} \left(\frac{\Delta\rho}{\rho_0} \right) \quad (5)$$

where $\Delta\rho$ is the density difference between planetary centre and surface caused by gravitational self-compression. A better approximation for α can be found by replacing ρ_0 by the average density $\bar{\rho}$ and K_0 by the average incompressibility \bar{K} . If the planet consists of chemical layers (each of which has constant mass as G changes) then $\Delta\rho/\bar{\rho}$ can be replaced by $\sum \Delta\rho_i/\bar{\rho}_i$, where $\Delta\rho_i$ is the density contrast across layer i of average density $\bar{\rho}_i$.

Univariant phase transitions (such as the olivine-spinel transition in the Earth and in Mars) cannot be treated this way, as the mass in each layer changes as G changes. For a homogeneous planet, the contribution to α because of a phase transition is

$$\alpha_{ph} = \frac{(\rho_1 - \rho_2)R_1(R_2^2 - R_1^2)}{2\rho_2 R^3} \quad (6)$$

in the limit of small self-gravitation, where $\rho = \rho_1$ for $0 \leq r \leq R_1$ and $\rho = \rho_2$ for $R_1 \leq r \leq R$.

For the Earth, equation (5) is a rather poor approximation and an extension of Birch analysis⁵⁵, including the olivine-spinel and spinel-postspinel transitions⁵⁶, gives $\alpha = 0.085 \pm 0.02$.

For Mars, the models of Okal and Anderson⁵⁷ (including the olivine-spinel transition) give $\alpha = 0.032$, whereas models incorporating a high pressure phase of magnetite⁵⁸ predict $\alpha \approx 0.028$. The martian moment of inertia is still uncertain⁵⁹, but $\alpha = 0.03 \pm 0.01$ encompasses all likely models.

Since Mercury provides the best constraint on the changes in R and G , the calculation for α has been done by both the simple method (equation (5)) and by the solution of equation (1) for several closely spaced values of G . For the differentiated models of Siegfried and Solomon⁶⁰ and their equations of state, the methods agree to within 20% and imply $\alpha = 0.02 \pm 0.005$. (The error is intended to indicate the likely uncertainty in the interior models of Mercury, given that the average density implies a predominantly iron composition).

For the Moon, any acceptable iron core has a negligible effect; and equation (5) applied to Ringwoods' models⁶¹ gives $\alpha = 0.004 \pm 0.001$.

The palaeoradii and these estimates for α give the upper limits to the rate of decrease of G listed in Table 3. Note that the limits for DMC are based on the limits for contraction of the planets, in accordance with our earlier discussion. To assess the validity of these limits, it is necessary to examine critically the assumption of hydrostatic equilibrium. Suppose that only an outer rigid lithosphere of thickness d violates hydrostatic equilibrium. As G decreases at constant R , the tensile stress in this lithosphere is about $3(\Delta G/G)\alpha K_0 R/d$. For $\Delta G = 0.03G$ (the upper limit implied by constant-mass Mercury), this stress exceeds 10 kbar, provided d is less than about 1,000 km (Earth, Mars), 500 km (Mercury), and 100 km (Moon). Since the lunar lithosphere is almost certainly much thicker than 100 km⁶², the allowable change in G might not affect the lunar surface. In contrast, the Mercurian mantle is only about 650 km thick⁶⁰, and the lithosphere is much thinner than this, as the presence of a large magnetic field suggests a thermally active planet with a large iron core^{63,64}.

If we exclude a fortuitous cancellation of thermal contraction and the expansion resulting from decreasing G in Mercury, then the upper limit of $8 \times 10^{-12} \text{ yr}^{-1}$ for the rate at which G decreases in a constant mass theory is realistic. This would seem to rule out the Dirac additive creation and Hoyle-Narlikar theories. The limit indicated by palaeomagnetic measurements on Earth is similar to that found from an analysis of radar observations in the inner Solar System^{65,66} and approaches the values predicted by the Dirac additive creation and Hoyle-Narlikar theories.

The upper limit for Dirac multiplicative creation of $2.5 \times 10^{-11} \text{ yr}^{-1}$ is a factor of 2 smaller than the value of $5 \times 10^{-11} \text{ yr}^{-1}$ indicated by the presently favoured value of Hubble's constant. This is a stronger constraint on the theory than other entirely different considerations⁶⁷⁻⁶⁹ have imposed.

West Antarctic ice sheet and CO₂ greenhouse effect: a threat of disaster

J. H. Mercer

Institute of Polar Studies, The Ohio State University, Columbus, Ohio 43210

If the global consumption of fossil fuels continues to grow at its present rate, atmospheric CO₂ content will double in about 50 years. Climatic models suggest that the resultant greenhouse-warming effect will be greatly magnified in high latitudes. The computed temperature rise at lat 80° S could start rapid deglaciation of West Antarctica, leading to a 5 m rise in sea level.

ATMOSPHERIC carbon dioxide traps some of the long-wave radiation emitted by the Earth's surface (principally near 15 μm wavelength), thereby tending to warm the troposphere. This so-called greenhouse effect has long been suspected^{1,2} but only recently, as the implications of a continuation of the current near-exponential growth of industrial CO₂ production have been realised, have many come to fear a disastrous climatic warming in the rather near future. In a recent report on the climatic effects of energy production, Revelle *et al.*³ conclude that industrial civilisation may soon have to decide whether or not to make the tremendous investment of capital and effort needed to change over from fossil fuels to other sources of energy. Bolin⁴, in hearings before the U.S. House of Representatives, points out that if all reserves of fossil fuel that are accessible by present techniques were burnt, thereby increasing atmospheric CO₂ content between five- and eightfold above its preindustrial level, the result would almost certainly be climatic disaster.

I contend that a major disaster—a rapid 5 m rise in sea level, caused by deglaciation of West Antarctica—may be imminent or in progress after atmospheric CO₂ content has only doubled. This concentration of CO₂ will be reached within about 50 years if fossil fuel continues to be consumed at its recent accelerating rate, or within about 200 years if consumption is held constant at today's level^{4,5}. Keeling and Bacastow⁶ believe that even if a policy of conversion to other sources of energy was started today and vigorously pursued, the global rate of consumption of fossil fuels would still double by the end of this century.

If so, the actual doubling time for atmospheric CO₂ content is likely to be nearer 50 than 200 years.

Many attempts have been made to estimate by climatic modelling the average global rise in temperature that would result from a doubling of atmosphere CO₂ content. The figures obtained have ranged from 0.7 K to 9.6 K, and Schneider⁷ has critically examined the models in an attempt to clear up the confusion created by these widely different estimates. He points out that some of the models give unrealistic results because they compute an equilibrium condition for the Earth's surface rather than for the Earth-atmosphere system as a whole. He stresses the advantages of radiative-convective models, which take into account vertical motions of the atmosphere and latent heat transport, and he compares the radiative-convective models of Rasool and Schneider⁸, who had computed an average global temperature rise of 0.8 K, with that of Manabe and Wetherald⁹ who had computed a rise of 2.3 K, later revising this to 2.9 K. He estimates that, using the most refined input of feedback mechanisms that is possible with present knowledge, globally-averaged temperatures would rise about 1.9 K. But, because some feedback mechanisms may have been improperly modelled, some (especially those involving changes in cloud cover and cloud top elevation) have been largely ignored because of our inability to do otherwise, and others perhaps remain unknown, he concludes that the best state of the art, order of magnitude estimate is that a doubling of atmospheric CO₂ content would raise average global temperature by 1.5–3 K. He believes that this estimate is as likely to be too low as too high.

More recently Augustsson and Ramanathan¹⁰, using a different modelling technique, and taking into account the previously ignored effect of bands of weak absorption by CO₂, have calculated that global temperatures would rise about 2 K. This, they note, is similar to Schneider's figure; they find this encouraging, but surprising and perhaps fortuitous because substantially different modelling techniques were used. Their one-dimensional model gives no information about differences between latitudinal zones, but the three-dimensional model of

Fig. 1 Computed rise in mean atmospheric temperature, as a function of latitude and elevation, that would result from a doubling of atmospheric CO_2 content (after Manabe and Wetherald⁹ who emphasise that, because of the various simplifications of the model, the quantitative aspects of the results should not be taken too seriously).

Manabe and Wetherald⁹ shows greatly magnified warming in high latitudes caused by the lack of vertical mixing, and by the feedback effect of decreased albedo as snow and sea ice cover recede: temperatures would rise by ~ 2 K between the equator and lat 30° north or south, by 4 K at lat 60° , by 7 K at lat 70° , and by > 10 K at lat 80° (Fig. 1). Schneider⁷ agrees that this effect is likely and points out that warming in the polar regions could be crucial because of their sensitivity to changes in the energy balance.

Manabe and Wetherald⁹ emphasise that because their model is highly simplified—it has idealised global topography, fixed cloudiness, no heat transport by ocean currents and no seasonal variability—these figures for the rise in temperature should not be taken at their face value. Smagorinsky¹¹ discusses the model and points out that seasonal variability is of fundamental importance in high latitudes because it determines the extent of snow and ice cover; if this factor, and the reactions of the oceans and clouds were taken into account, a very different result might be obtained; it is even possible that global cooling would be indicated. Keeling and Bacastow⁶ conclude that until the feedback effect of the slow response of subsurface ocean waters can be correctly modelled, the regional climatic changes that are of greatest interest to mankind will be hard to predict. Nevertheless, as Bolin⁴ points out, although the model of Manabe and Wetherald has serious shortcomings it is the most advanced that has yet been developed, and to gamble with the Earth's climate by ignoring it would be highly irresponsible. In the same vein Schneider¹² sums up the dilemma facing mankind: despite the crudities and inadequacies of present techniques for modelling the climatic effects of increasing atmospheric CO_2 content and the resultant doubts about the magnitude of the warming that would actually occur, we cannot afford to let the atmosphere carry out the experiment before taking action because if the results confirm the prognosis, and we should know one way or the other by the end of the century, it will be too late to remedy the situation on account of the long residence time of CO_2 in the atmosphere (Keeling and Bacastow⁶ estimate that, if all accessible fossil fuels were burnt, restoration of pre-industrial levels of CO_2 would take at least 10,000 yr).

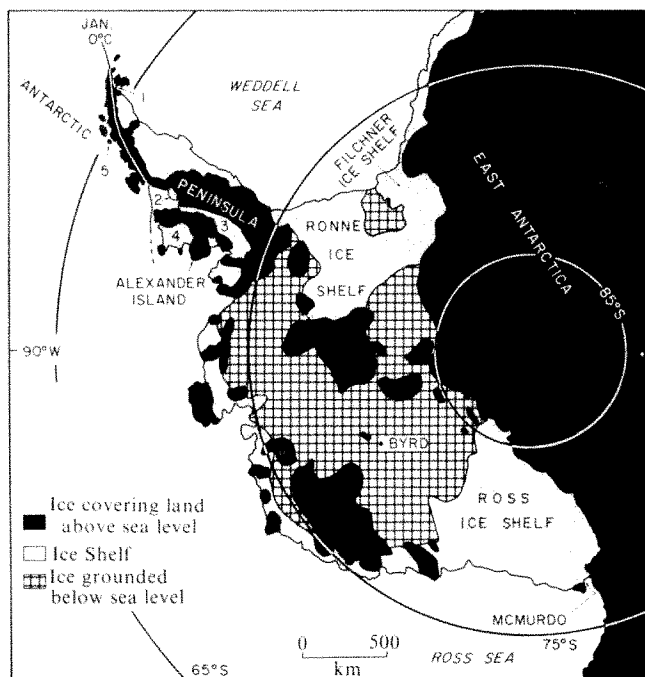

Is the CO_2 greenhouse effect detectable in recent climatic trends?

Since about 1940, temperatures over much of the Northern Hemisphere have dropped despite rising atmospheric CO_2 content. Broecker¹³ suggests that this may have lulled us into a sense of false security about the danger of increasing CO_2 levels; the cooling does not disprove or cast doubt on the CO_2 greenhouse-warming theory but is, he suspects, merely the effect of a natural cooling cycle that has overwhelmed the warming due to CO_2 , which he estimates has amounted to no more than 0.2°C for the past 30 years. He

believes that the quasi-cyclical pattern of climatic fluctuations in the recent past, which is shown by the oxygen isotope record from the Greenland Ice Sheet¹⁴, implies that this cooling will soon level out, to be followed by a period of rapid warming as the natural climatic trend is reinforced by the effects of increasing atmospheric CO_2 . In fact, the cooling since 1940 seems to have been mainly confined to middle and high latitudes in the Northern Hemisphere, and some investigators believe that the southern part of the Southern Hemisphere has warmed during the same interval. Damon and Kunen¹⁵ have studied climatic records from 67 Southern Hemisphere stations that meet certain specifications and that have records that go back to 1954 or earlier. They find that since 1943 temperatures have changed little between the equator and lat 45°S , except in Australia and New Zealand which, as other workers also point out^{16,17}, have warmed by about 1°C since the 1940s. South of lat 45°S , however, they conclude that average annual temperatures increased between the 1960–64 and 1970–74 pentads, particularly in West Antarctica where they rose about 2°C at Argentine Island (lat 65°S), McMurdo (lat 78°S), and Byrd (lat 80°S) (Fig 2). Thomas^{18,19} observation that temperatures at 10 m depth in the eastern part of the Ross Ice Shelf rose about 1°C between 1958 and 1972 confirms the warming trend in West Antarctica.

Damon and Kunen¹⁵ suggest that the climate of the Southern Hemisphere is now responding to the CO_2 greenhouse effect, whereas in the Northern Hemisphere this has recently been overwhelmed by cooling caused by man-made particulate pollution and also, possibly, from greater volcanic activity. Budd¹⁹, however, while noting the recent warming in West Antarctica, finds no clear evidence that Antarctica as a whole either warmed or cooled between 1958 and 1972; furthermore, at the South Pole 1976 was the coldest year since records began there in 1957²⁰. So far, apparently, despite recent regional warming over Australasia and West Antarctica, there is no unequivocal evidence for a global rise in temperature caused by increasing atmospheric CO_2 content. If Broecker's estimate is correct that average global CO_2 -caused warming would have amounted to no more than a fifth of a degree in the past 30 years, this is perhaps not surprising.

Fig. 2 West Antarctica, showing ice shelves, ice grounded below sea level, ice covering land above sea level, and position of the 0°C January isotherm in the Antarctic Peninsula (based on information up to the year 1962)²⁵. 1, Prince Gustav Channel; 2, Wordie Ice Shelf; 3, George VI Sound; 4, Wilkins Sound; 5, Argentine Island.

First disastrous consequence of rising CO₂ levels

Those who are most aware of the climatic dangers of increasing atmospheric CO₂ do not seem to view deglaciation in Antarctica as an immediate threat. For example, Schneider and Dickinson²¹, and Bolin⁴, believe that the Antarctic Ice Sheet will respond to climatic warming very slowly, during millennia, while Rotty and Budyko^{22,23} are more concerned with the shrinkage and eventual disappearance of the Arctic sea ice. Revelle *et al.*³ conclude that our present understanding of the Antarctic Ice Sheet is insufficient for us to forecast how it would be affected by global warming of several degrees. They believe that the direct effect of the warming would be minimal, but suggest that increased snowfall might eventually thicken the ice sheet enough to cause surging, perhaps resulting in deglaciation of West Antarctica. But, not only would effective thickening of the ice sheet require a long interval of increased snowfall, but also it is doubtful that a thickening ice sheet would surge. I believe that Revelle *et al.*³ underestimate the direct effect of moderate Antarctic warming, which would be likely to cause deglaciation of West Antarctica long before any significant thickening of the ice sheet could occur.

If present trends in fossil fuel consumption continue, and if the greenhouse warming effect of the resultant increasing atmospheric CO₂ is as great as the most advanced current models suggest, a critical level of warmth will have been passed in high southern latitudes 50 years from now, and deglaciation of West Antarctica will be imminent or in progress. Deglaciation would probably be rapid once it had started, and when complete would have led to a rise in sea level of about 5 m along most coasts. The reasons for this ominous situation lie in the unique characteristics of the West Antarctic ice sheet.

West Antarctic ice sheet's vulnerability to climatic warming

The Antarctic Ice Sheet consists of two unequal parts, with different histories and characteristics: the vast, long-established, mainly land-based ice sheet in East Antarctica, and the younger, much smaller marine ice sheet²⁴, grounded as much as 2,500 m below sea level in West Antarctica (Figs 2 and 3). Melting of the East Antarctic ice sheet would raise sea level by about 50 m, whereas melting of the West Antarctic ice sheet, much of which is only displacing ocean water, would raise sea level by no more than about 5 m on average²⁶ (Clark & Lingle²⁶ show that the sea level change would not be globally uniform).

When the Antarctic Ice Sheet formed while temperatures dropped during the late Cretaceous, there was an interval, during which temperatures dropped further, between the emplacement of the East Antarctic ice sheet in the late Miocene²⁷ and of the West Antarctic ice sheet, probably during the latest Miocene or earliest Pliocene²⁸. This was because the land-based East Antarctic ice sheet could form as a temperate glacier, whereas the marine West Antarctic ice sheet had to consist of cold ice from the start²⁵. (The thermal requirements of the West Antarctic ice sheet are discussed in more detail later.) Thus, in order to survive, the West Antarctic ice sheet needs colder summers—perhaps as much as 10 °C colder—than does the East Antarctic ice sheet, and is, therefore, more vulnerable to a rise in temperature. During sustained climatic warming, the Miocene–Pliocene sequence of glacial buildup would be reversed, and the West Antarctic ice sheet would be eliminated before the East Antarctic ice sheet was greatly affected. Fortunately, serious depletion of the East Antarctic ice sheet is a distant threat because, being land-based, it could retain a positive mass balance after climatic warming had converted it from a cold to a temperate glacier at low elevations. Even if further warming gave it a severely negative mass balance, it would waste away only slowly over millennia, by *in situ* melting, as the Laurentide Ice Sheet did 14–8,000 yr ago²⁹. The resultant rise

in sea level would cause considerable inconvenience, but would be gradual enough to allow coastal communities to adjust. This is apparently the type of deglaciation that Schneider and Dickinson²¹ and Bolin⁴ had in mind when they considered the effects of climatic warming on polar ice sheets; unfortunately, however, the West Antarctic ice sheet would be unlikely to shrink in this manner.

In contrast to the land-based East Antarctic ice sheet, the marine ice sheet in West Antarctica can exist only so long as its grounded portion is buttressed by fringing ice shelves; in particular, by the Ross and Filchner–Ronne ice shelves (Fig. 2). Thus any environmental change that diminished or destroyed these ice shelves would also diminish or destroy the ice grounded below sea level; as the ice shelf fronts receded southward, their grounding lines would also recede and the grounded ice sheet would shrink and thin. Eventually, after all ice shelves had disappeared, ice cover would be confined to areas above sea level, and glaciers would terminate in ice cliffs between high and low water levels^{25,30–32}.

Ice shelves are vulnerable to both oceanic and atmospheric warming. They will melt at the base if the water they are in contact with is above its freezing point; as Robin³¹ notes, they are absent from the coasts of the Antarctic Peninsula only where sea temperatures rise above –1.5 °C during the warmest month. (For water with 35‰ salinity, freezing point is about –1.9 °C at the surface and about –2.2 °C at 500 m depth³³). Melting will accelerate if a positive temperature gradient develops between the base and the surface; this will happen only if the ice shelf becomes temperate as rising air temperatures produce enough meltwater to percolate downwards and destroy the previous winter's cold wave. In fact temperate ice shelves do not seem to exist in nature, except possibly as short-lived features during climatic warming; Robin and Adie³¹ observe that all known ice shelves are cold, that is, below the pressure melting point at depth, and that their northern limit on the west coast of the Antarctic Peninsula lies a short distance south of the northernmost land glaciers that are cold at sea level. They conclude that a climatic warming above a critical level would remove all ice shelves and, consequently, all ice grounded below sea level, resulting in the deglaciation of most of West Antarctica.

The observations of Robin and Adie imply that where summers are warm enough to destroy the previous winter's cold wave in a glacier at sea level, ice shelves will be absent. In the Antarctic Peninsula the 0 °C isotherm for the warmest month (January), which trends south-west from the tip of the peninsula towards Alexander Island³⁵ (Fig. 2), is almost parallel to, and a short distance outside, the northern limit of ice shelves. Other aspects of the summer climate besides air temperature, particularly the duration and intensity of solar radiation, must also be involved in determining the northern limit of cold ice at sea level, and thus of the ice shelves, but the 0 °C isotherm for midsummer air temperature seems at least as realistic a climatic boundary for ice shelves as does, for example, the 10 °C midsummer isotherm that approximately marks the northern limit of trees³⁶. Most ice shelves, however, terminate considerably south of the 0 °C midsummer isotherm. Around the coasts of East Antarctica they are limited by the positions of the outermost lateral anchor points³⁷, but in West Antarctica neither high temperatures nor lack of anchor points prevent the northward expansion of the Ross and Filchner–Ronne ice shelves. The frontal positions of these large ice shelves depend mainly on the position of the grounding line of the West Antarctic ice sheet, and this is determined by water depth and, to a smaller extent, by snow accumulation rates.

Average midsummer air temperatures at the fronts of both the Ross and Filchner–Ronne ice shelves are now about –4 °C to –5 °C³⁵. Thus the deglaciation of West Antarctica that Robin and Adie³¹ foresaw would result from sufficient climatic warming would be unlikely to start until air temperatures had risen about 5 °C, bringing summer temperatures

Fig. 3 *a*, Antarctic ice cover today, and *b*, after a 5–10 °C warming.

over the Ross and Filchner–Ronne ice shelves up to those now prevailing in the northwestern Antarctic Peninsula. Once this level of comparative warmth had been reached, deglaciation would probably be rapid, perhaps catastrophically so, because even a small additional rise in temperature would affect a large expanse of gently sloping ice shelf. As Hughes³² graphically describes it, “a relatively minor climatic fluctuation along the ice shelf calving barrier can unleash dynamic processes independent of climate that cause calving bays to remorselessly carve out the living heart of a marine ice sheet.” An example of deglaciation by the calving bay mechanism was the extremely rapid disintegration of the central portion of the Laurentide Ice Sheet, centred over the present Hudson Bay, sometime between 8,000 and 7,500 BP, after thousands of years of slow recession on land³⁸.

The Ross and Filchner–Ronne ice shelves would probably be on the verge of receding southward if summer temperatures rose 5 °C at lat 80° S. The climatic model of Manabe and Wetherald⁹, for which year-round climatic uniformity is assumed, suggests a warming of more than 10 °C at lat 80° S after atmospheric CO₂ content has doubled; this concentration will perhaps be reached within 50 years. If this model is even approximately correct, rather drastic deglaciation should then be in progress in West Antarctica.

One warning sign that a dangerous warming is beginning in Antarctica will be the breakup of ice shelves in the Antarctic Peninsula just south of the recent January 0 °C isotherm; the ice shelf in Prince Gustav Channel on the east side of the peninsula, and the Wordie Ice Shelf, the ice shelf in George VI Sound, and the ice shelf in Wilkins Sound on the west side (Fig. 2). There is some evidence, not yet conclusive, that such a southward recession of the ice shelf limit in the Antarctic Peninsula has already begun; a comparison of LANDSAT imagery with earlier surveys has shown that between 1966 and 1974 nearly 600 km² or about one quarter of the Wordie Ice Shelf broke away, and the ice shelf in George VI Sound receded³⁹.

Fall in sea level by glacial growth

High latitude warming might well bring increased snowfall to Antarctica and perhaps to parts of Greenland also, as Revelle *et al.*³ suggest. This is far from certain, however, because although the warmer air masses could hold more moisture, cyclonic disturbances might decrease in number and intensity if, as present models indicate, the latitudinal temperature gradient decreased. To what extent deglaciation in West Antarctica would be offset by glacial buildup elsewhere is hard to estimate. Robin and Adie³¹ calculate that doubling the net annual accumulation rate on the East Antarctic ice sheet, which already reaches the coast, would increase its volume by no more than 10%. This, they estimate, would eventually result in a 4 m drop in sea level; however, they also conclude that the East Antarctic ice sheet would take several thousand years to reach its new equilibrium volume. Thus, if temperatures rose no further, warmth-induced deglaciation of West Antarctica might eventually be partially or even wholly offset

by thickening of the surviving ice sheets. It would be unwise, however, to rely on this buildup being rapid enough to avert a disastrous rise in sea level, and in any case, if temperatures continued to rise because of increasing atmospheric CO₂ content, glacial growth in East Antarctica would eventually cease.

Previous destruction of the West Antarctic ice sheet

Considerable evidence from the Southern Hemisphere suggests that the warmest part of the last interglacial (Sangamon–Eem) was warmer than the present interglacial has been so far; for instance, subantarctic seas were then warmer than they have been since (J. D. Hays, personal communication), and in Southern Chile chemical weathering was unusually intense⁴⁰. This warm interval—substage 5e, according to the sequence established by Emiliani⁴¹—was centred 120–125,000 yr ago⁴². If the West Antarctic ice sheet was absent at that time, the hypothesis that a rather moderate rise in temperature would destroy it would be strengthened.

I earlier suggested that the high sea level of the last interglacial (probably about +6 m) resulted mainly from deglaciation of West Antarctica when temperatures there rose too high for the survival of ice shelves²⁸. Deglaciation of West Antarctica alone would add a layer of water about 5 m deep over the area of the present world ocean. Later, Emiliani suggested that the high sea level resulted from deglaciation of Greenland, with minimal contribution from Antarctica, but this is highly unlikely because the marine West Antarctic ice sheet is much more vulnerable to climatic warming than is the land-based Greenland ice sheet.^{43,44}

A rise in eustatic sea level is not necessarily a glacio–eustatic rise, so that the high sea level of the last interglacial by no means proves that less ice was then present. Supporting evidence for the hypothesis came later when oxygen isotopic analyses of Core V 28-238 from the equatorial Pacific showed that the mass of the oceans during substage 5e was greater than it is today⁴². The isotopic difference between the Holocene and substage 5e was about what might be expected from melting of the West Antarctic ice sheet during substage 5e. Shackleton (personal communication) now believes that because planktic and not benthic foraminifera were analysed for substage 5e in Core V28-238, the isotopic composition may include a temperature effect. Thus, although the oceans did contain more water during substage 5e than they do now, just how much more is uncertain. Measurements being made on other deep sea cores should give more accurate figures in the near future.

Possible disintegration of West Antarctic ice sheet from non-climatic causes

Some workers^{45–48} believe that the West Antarctic ice sheet shrank at the end of the last glaciation when its grounding line receded as the result of the ~120 m eustatic rise in sea level. Others^{50,51}, however, believe that changes in the extent and thickness of the West Antarctic ice sheet since the last glacial age have been minor. In any case, with the larger Northern Hemisphere ice sheets gone, no further major shrinkage of the West Antarctic ice sheet as the result of rising sea level will occur in the near future.

Thomas and Weertman^{52,53} believe that the present West Antarctic ice sheet is inherently unstable and that, if it disintegrates, it will do so through mechanisms unconnected with climate. Hughes⁵⁴ agrees that such internal instability mechanisms are possible and could result in surges, but he also stresses the vulnerability of the ice sheet to climatic change. Weertman⁵³ suggests that the presence of ice streams draining the ice sheet is a premonition of a large-scale surge, the start of a process that may cause the West Antarctic ice sheet to discharge one third to one half of its volume into the oceans over, say, 100 years. The only occasion, however, during the last half

million years or so that the oxygen isotopic composition of the oceans implies the presence of less land ice than today is during substage 5e (ref. 42); that is, during an interval that was warmer than the Holocene. This strongly suggests cause and effect: the West Antarctic ice sheet was absent because of the high temperature. There is no evidence that the ice sheet has ever been seriously depleted by surges in the past and therefore, I believe, there is no reason to suppose that it will be in the future. Weertman may be right for the wrong reasons; the ice sheet is likely to disintegrate in the rather near future, but because of man-made climatic warming, not through surges resulting from internal instability mechanisms.

Conclusions

The present West Antarctic ice sheet is reasonably secure against all instability mechanisms except for climatic warming above a critical and—for the Pleistocene—exceptional level. In the natural course of events, this level of warmth might be reached about once in half a million years, perhaps as a consequence of an unusual combination of the astronomic factors that seem to be responsible for the timing of the major glacial-interglacial climatic changes⁵⁵. Furthermore, because the present interglacial has apparently passed its natural peak of warmth—this was probably reached about 9,400 yr ago in the Southern Hemisphere⁵⁵—deglaciation of West Antarctica would not occur in the foreseeable future without Man's injection of massive amounts of industrial CO₂ into the atmosphere.

If the recent growth rate of fossil fuel consumption continues, atmospheric CO₂ content is expected to double in about 50 yr. Present models of the climatic effects of this doubling compute a rise in temperature that could cause rapid deglaciation of West Antarctica, leading to a 5 m rise in sea level. Although the models are known to be crude and over-simplified, so that the climatic changes that will actually occur will no doubt differ considerably from their estimates, there is, at present, no way of knowing whether the models err on the optimistic or pessimistic side.

If the CO₂ greenhouse effect is magnified in high latitudes, as now seems likely, deglaciation of West Antarctica would probably be the first disastrous result of continued fossil fuel consumption. A disquieting thought is that if the present highly simplified climatic models are even approximately correct, this deglaciation may be part of the price that must be paid in order to buy enough time for industrial civilisation to make the changeover from fossil fuels to other sources of energy. If so, major dislocations in coastal cities, and submergence of low-lying areas such as much of Florida and the Netherlands, lies ahead. More sophisticated climatic modelling may show that the outlook is less alarming than this, but on the other hand, it may show that the situation is even more threatening. The urgent need for this sophisticated modelling is evident.

One of the warning signs that a dangerous warming trend is under way in Antarctica will be the breakup of ice shelves

on both coasts of the Antarctic Peninsula, starting with the northernmost and extending gradually southward. These ice shelves should be regularly monitored by LANDSAT imagery.

I thank I. M. Whillans for helpful comments.

Can a myosin molecule bind to two actin filaments?

Gerald Offer & Arthur Elliott

Department of Biophysics, King's College, 26-29 Drury Lane, London WC2, UK

It is suggested that in striated muscles the two heads of one myosin molecule are able to interact with different actin filaments. This would provide a simple explanation for the appearance and arrangement of cross-bridges in insect flight muscle in rigor.

THE myosin molecule has two globular heads attached at one end of a fibrous tail¹. During muscle contraction the heads are thought to bind to actin filaments and produce tension by tilting², but the way in which this is shared by the two heads is not known. It is widely supposed that the two heads of one myosin molecule interact with neighbouring subunits in the

Table 1 Retention of phosphate by hydrolytic precipitation products of aluminium collected from systems aged for 40 d in the absence and in the presence of citric acid

Suspension pH at equilibrium	$\mu\text{M P}$ retained per g sample		
	Citric acid concentration (M)		
	0	10^{-6}	10^{-4}
4.0	370	745	1,205
5.0	330	685	1,180
6.0	270	560	1,060
7.0	210	435	775
8.0	165	335	575

The preparation of the hydrolytic precipitation products of aluminium starting from an initial aluminium concentration of 1.10×10^{-3} M and the OH/Al molar ratio of 3.0 in the absence and in the presence of 10^{-6} M and 10^{-4} M citric acid has been described elsewhere⁹. Retention of phosphate was determined by shaking 50 mg of precipitation products in 50 ml of 0.1 M KCl solution containing 1.0×10^{-5} M KH_2PO_4 for 24 h at 25 °C. The data are deduced from a plot of $\mu\text{M P}$ retained per g sample against pH of the equilibrium suspension.

aluminium ions in aqueous solution^{10,11} and as a result of the occupation of coordination sites of aluminium by citrate during the formation of the precipitated products, distortion in the arrangement of hexagonal ring units normally found in crystalline aluminium hydroxides is bound to occur. The distortion as shown by X-ray diffraction analyses and electron microscopic observations was sufficient to impart a rough surface to the precipitation products and to cause the products formed in the presence of 10^{-6} – 10^{-4} M citric acid to be noncrystalline to X rays⁹. The mechanisms of adsorption of phosphate on hydrated aluminium oxides, on the basis of existing information¹², involve either the displacement of H_2O at positive sites or OH at negative sites. The formation of these phosphate retention sites on the surfaces of hydrolytic reaction products of aluminium would thus be promoted by the structural distortion effect of citric acid during the hydrolytic precipitation process. Moreover, the noncrystalline nature of the products enhances their specific surface (Table 2). This increase in specific surface of the products coupled with their noncrystalline nature and thus reactive sites for phosphate retention would apparently, at the low concentrations of citric acid, more than compensate the blocking of retention sites by citric acid and explains why the retention of phosphate by the products precipitated in the presence of citric acid is more extensive than in its absence.

The capacity of the noncrystalline solid phase products precipitated in the presence of 10^{-4} M citric acid to retain phosphate is not substantially diminished by an ageing period of 40 d (Fig. 1). On the other hand, the uptake of phosphate by the corresponding products formed in the absence of citric acid is considerably reduced after 40 d, for example, from 675 to 370 $\mu\text{M P}$ per g at pH 4.0 or from 270 to 165 $\mu\text{M P}$ per g at pH 8.0 (Fig. 1). Noncrystalline

aluminium hydroxides precipitated in the absence of interfering ions are very unstable and revert rapidly to the crystalline state¹⁴. On reversion to their crystalline state the specific surface of the aluminium hydroxides is considerably reduced (Table 2) with a concomitant decrease in the active sites for phosphate retention. In the presence of citric acid, the occupation of coordination sites by citrate would retard the reversion of the precipitation products to the crystalline state as that would require the removal of citrate from within the structure. The maintenance of the noncrystalline state with an accompanying high specific surface (Table 2) by citric acid would thus help to stabilise the high phosphate retention capacities of noncrystalline aluminium hydroxides.

**Fig. 1** Retention of phosphate by hydrolytic reaction products of aluminium formed in systems at the initial aluminium concentration of 1.10×10^{-3} M and OH/Al molar ratio of 3.0 in the absence (dashed line) and in the presence of 10^{-4} M citric acid (solid line) as a function of pH and time. Phosphate retention was determined as outlined in Table 1. \circ and \square , after 1 d; \times and \triangle , after 40 d.

Under natural environments, absolute elimination of low molecular weight biochemicals, such as citric acid, is seldom achieved and it is more realistic to believe that the hydrolytic reaction products of aluminium in soils and aquatic sediments are generally formed in the presence of minute but measurable quantities of biochemical compounds. Previous investigations^{5–8} have only reported the tendency of these biochemical compounds to reduce anion uptake by hydrated aluminium oxides through competition with the anions for adsorption sites. The present study provides direct evidence that they also enhance the retention of anions such as phosphate by the hydrolytic reaction products of aluminium through their promoting effects on the formation of noncrystalline aluminium hydroxides. In nature, therefore, the low molecular weight organic compounds have a dual role of hindering and promoting anion retention by the hydrated aluminium oxides depending on the mechanisms of their interfering reactions. This finding should be of fundamental importance not only in understanding the basic colloidal chemistry of aluminium but also in the transport and fate of nutrient and pollutant anions in terrestrial and aquatic ecosystems.

Limited response of the K–Ar system to the Nordlinger Ries giant meteorite impact

For the proper interpretation of radiometric rock ages it is important to know which processes are able to reset radioactive clocks. In particular, the resetting by intense shock effects is significant in lunar chronology because most lunar highland rocks are impact breccias produced in the course of multiple large meteorite impacts. For the important K–Ar scheme, we have dated variously shocked samples from ejecta and from a drill core through one of the best documented terrestrial meteorite craters the Nordlinger Ries (Southern Germany)¹. From K–Ar and fission track dating of thoroughly melted impact glasses the 24 km diameter Ries crater was found to have formed 14.7 ± 0.7 Myr ago by meteorite impact into the variscian bedrock (for summary of ages see ref. 2). The modern version of K–Ar dating (^{39}Ar – ^{40}Ar technique) can reveal quantitative information about partial losses of radiogenic argon (fractional resetting) in addition to yielding ages eventually not affected by these gas losses^{3,4}. We have applied this dating technique to mineral separates (hornblende, biotite, chlorite) from ejecta, fall-back breccias and underlying bedrock of the Ries Crater, including drill core samples taken at depths up to 1,201 m (ref. 1). The samples exhibit various degrees of mechanical strain (from ~ 10 kbar up to > 400 kbar shock pressure). Apart from the thoroughly molten glasses which reproduced the impact age of ~ 14.7 Myr, we found that all other rocks involved in the impact irrespective of the degree of shock metamorphism and within the limits of error, yield the same ^{39}Ar – ^{40}Ar age of 313 ± 3 Myr, probably the age of the bedrock. Apparently, rocks exposed to the very intense shock effects frequent on the Moon give reliable K–Ar ages when measured as K–Ar plateau ages. Age resetting, if present, probably results from heating associated with such impacts. In the case of the Ries, we found from the diffusion characteristics of argon that the post-shock temperature of the crystalline fragments within the suevite layer has not exceeded 600 °C.

Mineral separates were used to study the effect of shock on different minerals. We separated hornblende, biotite, and chlorite from the low grade metamorphic amphibolites and gneisses which occur as crystalline fragments imbedded in the suevite fall-back breccia above the crater bottom at 602 m depth, and as massive crystalline rocks below the crater bottom as well as in the crystalline wall of the crater (sample Meyer's Keller)¹.

The crystalline rocks from the drill core are weakly shocked and show impact features, (like, for example, planar elements) typical of shock pressures between 10 and 200 kbar (stage '0' and '1' of shock metamorphism)^{5–7}. The crater wall amphibolite (Meyer's Keller) and the gneiss from ejected suevite sampled at Otting display shock effects of stage 2 (~ 300 –450 kbar). All samples dated are listed in Table 1, including a melted impact glass and a moldavite that is, a tektite produced in the Ries impact event.

The experimental procedures applied in the ^{39}Ar – ^{40}Ar analysis are basically the same as those applied by us in dating lunar and meteoritic samples⁸. The samples obtained a fast neutron irradiation (FR2-reactor, Karlsruhe) to convert a part of the ^{39}K to the 269 yr- ^{39}Ar as a measure of the K in the sample.

Afterwards, the samples were degassed by stepwise heating from 400 to 1,500 °C (6–12 steps) and the Ar isotopes (Ar^{36} – 40) were measured by mass spectrometry. The ^{40}Ar to ^{39}Ar ratios obtained for each temperature fraction were converted into K–Ar ages by means of a muscovite monitor (Bern M4, $t = 18.0 \pm 0.2$ Myr) (ref. 9) irradiated together with the sample.

Two typical age spectra are shown in Fig. 1. In the absence of Ar-diffusion losses, an age plateau is obtained throughout essentially the whole range of degassing temperatures (Fig. 1a, hornblende from the crater bottom), whereas with the Ar-losses the geologically significant age plateau starts at intermediate temperatures and the low temperature fractions have reduced apparent K–Ar ages (Fig. 1b) ejecta from Otting.

A summary of results is given in Table 1. The character of the age spectra can be visualised from the error of the plateau age, the plateau range, and the percentage of gas loss. With the exception of the impact glass and the moldavite, both of which gave the impact age, 14.7 Myr, all samples yield plateau ages of approximately 313 Myr. The samples included depths > 700 m where the effect of the impact is minimal⁵. The average age 313 ± 3 Myr is probably the age of the basement rock. The age obtained represents the first direct dating of the pre-Ries basement rock.

The uniformity of plateau ages from all depths (above and below the crater bottom) suggests that the impact process involving enormous amounts of energy¹⁰ did not effectively disturb the K–Ar system of hornblende or biotite. This is true for ejected material as well as for crystalline inclusions in both high and low temperature suevite, and agrees with the experimental results of Davis¹¹ who demonstrated in laboratory experiments (65–270 kbar) that shock pressure alone has little influence on the K–Ar system.

For natural impacts, fractional age reductions have been observed at shock pressures above 200 kbar for anorthosites

Fig. 1 ^{40}Ar to ^{39}Ar age spectra for hornblende from the crater bottom (a, H 603) and for suevite ejecta sampled at Otting (b, HO). Each data bar represents one release fraction in the incremental heating procedure, beginning at 450 °C at the left and ending with 1500 °C at the right end. The amount of gas released in the various fractions is reflected in the widths of the bars, expressed as proportion of the total ^{39}Ar contained in the sample. The measured ^{40}Ar to ^{39}Ar ratios are transformed into apparent K–Ar ages using a monitor irradiated together with the samples. H 603 exhibits a nearly perfect age plateau comprising 94% of the total argon release. Sample HO has lost 12.9% of its radiogenic argon from the less retentive sites (lower degassing temperatures), but the plateau age remains undisturbed and is properly defined by the higher temperature fractions, in spite of a shock pressure exceeding 400 kbar.

Table 1 Summary of ^{40}Ar - ^{39}Ar results for Ries crater samples

Position*	SAMPLE Parent rock	K [%]	Total $^{40}\text{Ar}_{\text{rad}}$ [$10^{-6}\text{cm}^3\text{g}^{-1}$]	Total $^{40}\text{Ar}_{\text{atm}}$ [%]	Total K-Ar-age [Myr]	Plateau age [Myr]	Plateau range [%- %]	^{40}Ar loss [%]	Shock pressure [kbar]

*H = hornblende; B = biotite; C = chlorite; G = glass; MK = Meyer's Keller, crater wall; O = Otting; numbers indicate the depth in metres within the drill core.

Typical sample weights are 200-500 mg, except B 401 (5 mg). The K-content (error $\pm 2.5\%$) follows from the total reactor produced ^{39}Ar and the monitor derived conversion factor. Atmospheric ^{40}Ar is subtracted on the basis of ^{36}Ar (its relative magnitude is given in % of total ^{40}Ar). The total ('conventional') K-Ar age is derived from the integral $^{40}\text{Ar}_{\text{rad}}$ and ^{39}Ar quantities for all temperature fractions. In case of gas loss, it is lower than the plateau age. The error of the plateau age is the standard mean deviation of the ages of the plateau fractions. 'Plateau range' indicates the extension of those fractions which define the plateau age. These entries allow one to visualise the age spectra without explicit figure, examples for HO and H 603 are shown in Fig. 1. The shock pressure is estimated from microscopic inspection following the criteria of Engelhardt *et al.*⁶. Note the absence of a correlation between gas loss and shock pressure. Within the limits of error, essentially all samples yield the same age of $\approx 313 \pm 3$ Myr except the thoroughly molten glasses GO and GM which reproduced the impact age of 14.7 Myr.

from the 30 km Manicouagan structure (conventional K-Ar dating) (ref. 12) and for gneiss and feldspar from the 4 km Brent Crater (conventional K-Ar dating¹³, ^{39}Ar - ^{40}Ar dating¹⁴). This contrasts with the Ries observation of unreddened bedrock ages up to an above 400 kbar (Otting) not only for resistant hornblende but also for biotite. At both the Manicouagan and Brent Craters, samples from a recrystallised melt layer were studied, and probably means that age reductions observed for Manicouagan and Brent Craters are related to a thermal event. From the Ries K-Ar ages we conclude that shock pressure *per se* even as high as 400 kbar does not cause any significant argon loss. Consequently, any eventual age changes caused by meteorite impacts must be related to the temperature elevations associated with the impact and the rate of heat dissipation afterwards.

The peak temperature for the Ries fall-back breccia may be estimated. The common onset temperature, 800 °C, of the age plateaux of crystalline inclusions indicates that the inclusions were never heated above that temperature for any appreciable lengths of time (~ days). This upper limit temperature can be reduced to 600 °C by a model calculation for the cooling history of the suevite layer and an estimate of the hornblende activation energies from the stepwise heating argon release pattern. A 500 °C lower limit has been inferred by Wagner¹⁵ from the thermal stability and the degree of annealing of U-fission tracks in titanite and apatite from the ejected suevite from Otting. Apparently, the Ries ejecta was heated to 550 ± 50 °C at the time of impact.

Alternative ^{210}Pb dating: results from the New Guinea Highlands and Lough Erne

RECENT lake sediments can be dated using ^{210}Pb and fall-out ^{137}Cs . Pennington *et al.*¹, and Robbins and Edgington² have set out the assumptions used in calculating dates and estimating accumulation rates from the declining concentration of unsupported ^{210}Pb in the near-surface sediments of Bleham Tarn and Lake Michigan respectively. In both cases, as in other papers^{3,4}, an essential assumption is a constant initial concentration (c.i.c.) of unsupported ^{210}Pb per unit dry weight in the sediment at each depth, whether or not any variations may have occurred in the rate of accumulation. This assumption requires that in undisturbed cores, unsupported ^{210}Pb concentrations should always decline monotonically with depth. Figure 1 shows unsupported ^{210}Pb concentrations in cores from Lough Erne, Northern Ireland and Lake Ipea, Papua New Guinea. The profiles are 'kinked' and show at one or more points, a marked increase in unsupported ^{210}Pb concentration with depth. The levels at which this occurs in the cores range from 6 to 30 cm. The increases cannot, therefore, be the result of the anomalously low surface concentrations noted elsewhere⁴. Associated biological, chemical and geophysical studies show that the profiles have not been significantly disturbed by physical or biological mixing. These profiles are not consistent with the c.i.c. deposition model and are

Fig. 1 Unsupported ^{210}Pb concentration against depth in cores from Lough Erne, Northern Ireland, and Lake Ipea, Papua New Guinea. a, Lower Lough Erne, profile SM1; b, Lower Lough Erne profile FM1; c, Upper Lough Erne profile FM2; d, Lake Ipea, Core 1.

regarded as evidence for the dilution of unsupported ^{210}Pb by accelerated sediment accumulation. If such dilution has taken place without leading to a kink in ^{210}Pb concentrations, the assumption of c.i.c. will lead to underestimation of the true age of the sediment below the onset of acceleration. In the case of the 'kinked' profiles, dates are not calculable using the c.i.c. deposition model alone. We have adopted an alternative approach to calculating ^{210}Pb dates using as our main assumption a constant rate of supply (c.r.s.) of unsupported ^{210}Pb to the sediment per unit time and deriving dates from the integrated activity of the radionuclide. Previous authors have referred to the possibility

of calculating dates using this assumption^{5,6} but have not given a full account of the method or evaluated the results of its application. Details of the methods used here are set out elsewhere⁷. This paper compares and briefly evaluates the two alternative models as applied to the sediments of Lough Erne and Lakes Ipea and Egari. The c.r.s. based dates obtained have been compared with those derived either from c.i.c. based ^{210}Pb dates or, in the case of the 'kinked' profiles, from a combination of ^{137}Cs dating⁸ and c.i.c. based calculations. Figure 2 plots the resulting age against depth curves from Lough Erne, Fig. 3, some of the results from Lakes Ipea and Egari.

Fig. 2 Alternative ^{210}Pb based age against depth curves from three cores from Lough Erne, Northern Ireland. The standard errors are shown for the c.i.c. based profiles only. For cores b, FM1 and a, FM2 the strongly 'kinked' unsupported ^{210}Pb concentration profiles above 30 cm (see Fig. 1) make it impossible to derive c.i.c. based age against depth curves above this level. c, SM1. The alternative dates for the diatom assemblage change are marked on the timescale at the base of each plot.

Diagrams of diatom frequency have been completed for all three Lough Erne cores. The main change in diatom assemblages in each core is marked on Fig. 2. In each case, at this stage in the core, the proportion of planktonic diatoms expands and the concentration of frustules (cm^{-3} fresh weight) begins to increase. Using the ^{137}Cs and c.i.c. based age/depth curves, the age of this change ranges from ~1935 in core FM1 to ~1950 in core SM1, both from the Lower Lough. Using the c.r.s. model, dates in all three cores lie between 1907 and 1914.

On the basis of both calculations, sediments at 24.5 cm in SM1 and at 47 cm in FM1 seem to be contemporary. It is therefore possible to normalise these two profiles approximately, with regard to age. The c.i.c. model would require either that the ratio of concentrations at contemporaneous depths in the two sites to be constant or, because the dry weight accumulation rate above this level in FM1 is over three times as fast as in SM1, that the cumulative residual unsupported ^{210}Pb values in FM1 be greatly in excess of those in SM1. The ratio of concentrations between FM1 and SM1 varies from 2.3 : 1 to 4 : 1. Moreover, Fig. 4 shows that

each lake and, in both cases, the first schemes were installed around the turn of the century.

The presence of a synchronous volcanic ash layer in the recent sediments of Lakes Ipea and Egari makes it possible to identify two points at which the sediments for the two lakes are exactly contemporaneous—the surface mud and the mud in contact with the volcanic ash. Assuming a c.i.c. of unsupported ^{210}Pb implies that for all stages of deposition known to be synchronous between the two sites, the ratio between the concentrations of unsupported ^{210}Pb at the two lakes must be the same. Figure 5 shows that this is not the case; for example, in recent times the concentration at Egari has been around three times that at Ipea whereas the ratio is close to one during the period just after the ash fall. Though not compatible with the c.i.c. model this evidence is consistent with a c.r.s. model in which unsupported ^{210}Pb is diluted by more rapidly accelerating accumulation at Ipea than at Egari.

Geochemical studies (Blong, personal communication) have confirmed that the source of the most recent ash fall recorded in the Ipea and Egari sediments, as well as exten-

Fig. 3 Alternative ^{210}Pb based age against depth curves for *a*, core 5 from lakes Egari; and *b*, core 4 Ipea in the Highlands of Papua New Guinea. The ^{137}Cs age estimate takes into account the lag in peak fall-out between hemispheres. The upper peaked section of the c.r.s. based age against depth curve from Ipea has been obtained from measurements on core I for which detailed recent data are available; below this level, the data from the parallel adjacent core 4 have been used since at the lowest levels the ^{210}Pb measurements for core I are somewhat high when compared with mutually consistent profiles from the two sites.

the curves and cumulative residual unsupported ^{210}Pb values are almost identical and hence consistent with the c.r.s. model in which the rate of supply of unsupported ^{210}Pb to each site has been comparable, despite the difference in the rate of sediment accumulation.

No firm independent evidence of age is available for any of the recent Lough Erne sediments. The change in the diatom record noted above and redated to around 1910 indicates increasingly eutrophic conditions. It parallels that also dated to the early part of the twentieth century in Lough Neagh⁹. The most likely cause of this is the installation of sewerage schemes within the drainage basins of

sively elsewhere in the New Guinea Highlands, was Long Island some 400 km to the east. Analysis of historical records has shown that the period during which a major eruption in Long Island could have taken place ended long enough before 1827 to have left no obvious major traces on the landscape of the island¹⁰. Since then, the island has been frequently visited and its state well documented by Western observers. Several radiocarbon dates on terrestrial material associated with the ash placed its age at ~250 BP¹¹. Both lines of evidence point to an eighteenth century date and they are quite incompatible with the original c.i.c. based estimates which averaged ~AD1860. The four recalculated

Fig. 4 Cumulative total residual unsupported ^{210}Pb content for Lower Lough Erne cores FM1 (○) and SM1 (+) normalised to a correlated depth.

^{210}Pb profiles from Lakes Ipea and Egari regarded as mutually consistent on internal evidence give an age range between 1800 and 1840 and an average age of 1814. This date is within the time range possible on documentary grounds and much closer to the ^{14}C dates than were the original ^{210}Pb estimates.

Where accumulated rates have not changed over the last 150 years both the c.i.c. and the c.r.s. models will give identical and possibly reliable dates. The data presented

Fig. 5 Unsupported ^{210}Pb concentrations from Egari core 5 (solid line) and Ipea core 1 (dashed line) normalised for depth (×) by the synchronous volcanic ash layer common to both sediment profiles.

here suggest that in a lake where accumulation rates have accelerated, the c.r.s. model may provide dates which are more consistent on internal grounds and more compatible with existing external evidence.

Subaqueous sulphur lake in Volcan Poas

GREENISH amorphous sulphur particles are present at all levels immediately around the crater of Volcan Poas. The eruptive plumes of the mild submarine volcanism which characterises this volcano, are charged with these particles. We suggest here that they are strong evidence that a lake of molten sulphur exists, or is formed temporarily before an eruption, below the existing lake of water in the crater. We have collected many samples of greenish amorphous sulphur, with various quantities of admixed ash from regions all around the crater, noting some concentrations in the east-west prevailing wind directions. Figure 1 shows sulphur specimens and their morphology; Fig. 2 gives a profile of the crater; Fig. 3 shows approximate outlines of areas in which sulphur samples are found. Table 1 gives approximate analyses of representative samples.

Volcan Poas has been in a state of mild eruptive activity for about two centuries. Its usual activity is similar to shallow submarine volcanism. At intervals ranging from several times a month to several times an hour a plume arises from the approximate centre of the crater lake and ascends to heights varying from a few metres to 500 m or more. The plume is laden with particulate matter and may appear black or greenish. At much longer intervals, more violent eruptions producing grey ash, scoria, plastic lavas and bombs will occur. The most recent of these occurred in November 1976, and spread a mantle of grey ash for some kilometres to the west of the crater.

We shall look at the plume eruptions and their similarity to submarine volcanism, and we shall explain them using an approach¹ which may be generally applicable. All active volcanic structures contain a stack, or pile, of immiscible liquids separated by more or less definite boundaries; within each level processes of heat and mass transfer may occur by conduction and convection; bubbles may form, grow,

Fig. 1 Samples of amorphous sulphur from Volcan Poas. Ash content high in sample at upper left. Coin diameter = 1.5 cm.

rise and attach to upper boundaries, or disappear; processes of dispersion, sedimentation and crystallisation develop within layers. Across boundaries, or in boundary layers, fluxes of mass, heat, bubbles, crystals, and so on may occur. When the local vapour pressure within a particular level exceeds the hydrostatic pressure at that level, and the temperature distribution above will permit the growth of a vapour-filled cavity, then a suitable disturbance may initiate the vaporisation expansion wave which supports the growth of a plume, and an explosive eruption will take place.

In the present example, we consider the volcanic pile to be similar to that for shallow submarine volcanism. This assumption implies a volcanic pile with dry magmas below, more volatile magmas above these, then a crust or plastic layer, water-rich muds and clays, and water suspensions grading from heavily laden to lightly laden in the upward direction.

In Fig. 1 the sulphur samples all show evidence of a fluid dynamic eruptive process. The plume gases entrain and interact with molten or plastic, liquid sulphur by means of the reverse flows around the deformable fluid particles being accelerated by the vertical jet in the plume. Representative particles of the collection show elongations, separations into branches with ball-like terminations, twisted streamline configurations, deformed spheres, tiny spherical droplets, plastic masses with considerable ash content; and there exist some of all these types with vesiculated surfaces and interiors. These latter were probably burning during the eruption, over at least part of their trajectories.

Experiments in which existing pieces of our collection are set on fire show a clear blue flame characteristic of sulphur, produce SO_2 fumes, and leave very little residual ash. We observe vesiculation both of the surface and of the interior under the flame.

According to accounts of the rangers at Volcan Poas National Park, bushes at the high plateau level, 300–500 m, above the lake, were set on fire. We take the region devoid of living vegetation as the area covered, during various eruptions, by sulphur particles. In a circle of radius 1/2 mile around the lake centre, the density of sulphur particles suggests that several hundred tons of sulphur are lying on the surface or have been washed into the river courses by the heavy rains of the wet season.

The distribution with height, and the change from high sulphur content at lower altitudes, to less sulphur and more ash at the upper altitudes above the lake suggests that the distribution in the columnar plume reflects a similar distribution in sulphur content of the portion of the volcanic pile where sulphur occurs.

We believe that the evidence available justifies the assumption that there is a level, or lake, of molten sulphur below the existing lake of water. The specific gravity of sulphur, 1.9–2.0, is intermediate between that of andesitic magma, 2.5–2.7, and that of pure water. We have no evidence for the average specific gravity of a water-rich clay or mud of volcanic ash, but we assume that values intermediate in the range 1.0–2.0 can be encountered. Therefore, to our model of the volcanic pile we add, immediately above the crusted magma, a layer of molten sulphur on which floats a layer of water-rich volcanic ash and lapilli. Above this layer lies the crater lake which from its greenish appearance carries a suspended load of sulphur and ash varying with time. One of the precursor signs of an imminent eruption is the appearance of a grayish spot, 25–50 m in diameter, in the centre of the lake. We take this to be

Fig. 2 Profile of the crater. Arrow indicates the position of the plume.

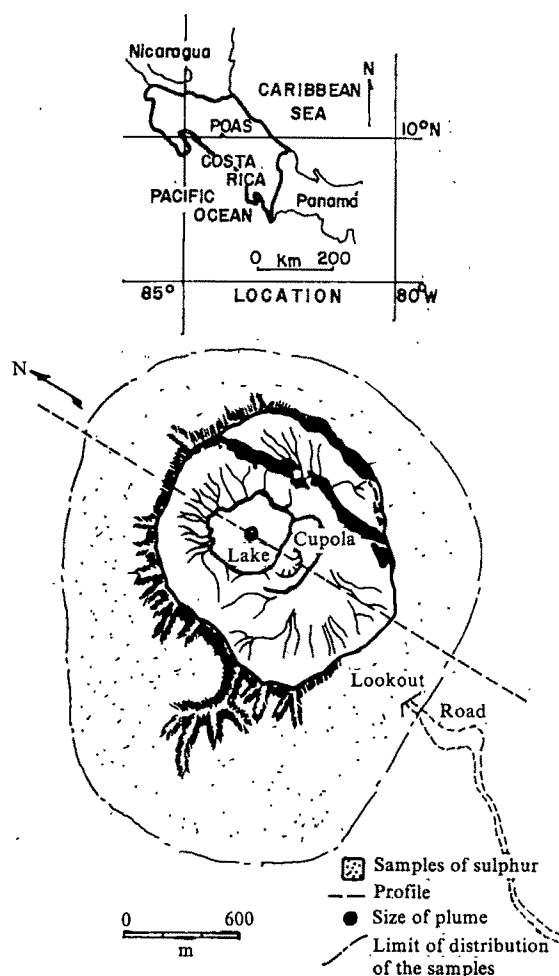

Fig. 3 Map of the crater.

an indication of convective processes that carry portions of the underlying sulphur-ash levels to the surface.

We can only speculate how the plume forms and the eruption occurs. Because the plume is laden with molten sulphur-ash particles some of which catch fire on exposure to air, we may presume high temperatures in the sulphur layer, probably higher than the normal boiling point, 444 °C, in the lowermost portions. If the propulsive fluid for the eruption is sulphur vapour, then temperatures much higher than the boiling point will be encountered at the level between solid or plastic magma and molten sulphur.

A possible mechanism for production of an eruption, other than the gradual increase in temperature of the column during the hydrostatic phase, would be an overturning instability brought about by an increase in density of the mud deposited by sedimentation from above. As the density of the overlying mud increases to near equality with that of the molten sulphur, an overturning instability would be possible that would rapidly expose high temperature sulphur to overlying water and bring about an explosion similar to those noticed in fuel-coolant interactions².

Table 1 Analysis of sulphur content of representative samples

Sample	1	2	3	4	5
Weight % sulphur	16	85	98	98+	99

We think that other sulphur producing volcanoes, particularly those of andesitic type, should be examined for signs of the existence of a lake of molten sulphur in the volcanic pile.

The Soufrière Crater Lake as a calorimeter

IN 1971-72, $8 \times 10^7 \text{ m}^3$ of basaltic andesite lava were extruded into the summit crater of Soufrière volcano, St Vincent¹. The first half of the eruption took place entirely subaqueously and the second half almost entirely so and these facts have provided us with an unusual opportunity to carry out quantitative studies of several aspects of the eruption. Before the eruption the crater contained $7.5 \times 10^7 \text{ m}^3$ of water and the potential of this lake as a giant condenser of volcanic gases has already been demonstrated². We show here that by treating the crater lake as a giant calorimeter we can make reasonably accurate estimates of the rate at which heat was lost by the erupted lava and hence draw important conclusions about its mode of extrusion. The heat transfer data are consistent with the idea that the lava mass accumulated by the multiple extrusion of numerous small lava bodies¹ rather than by extrusion of a single domelike mass, as has been proposed by other workers^{3, 4}.

The eruption of 1971-72 began some time in early October 1971 and until November 20, 1971 it continued entirely subaqueously. Before the eruption the crater lake contained $7.5 \times 10^{10} \text{ kg}$ of water at a temperature close to the mean ambient temperature of 22 °C. Seepage into the crater walls and normal evaporation were balanced almost exactly by precipitation. By the time that lava began to emerge through the surface of the lake on 20 November 1971, the mass of water in the lake had decreased to $5.7 \times 10^{10} \text{ kg}$. The temperature at the edge of the lake was 82 °C on 2 November and probably was maintained at at least this value for at least 1 month before 20 November. Throughout this early part of the eruption the temperature of the streams and springs on the outer flanks of the volcano was monitored both by aerial infrared photography and by manual measurements and we found no evidence that seepage from the lake had increased. We therefore conclude that $1.8 \times 10^{10} \text{ kg}$ of water were lost by excess evaporation caused by heat input from the lava. Heat supplied to the crater lake up to 20 November therefore includes four main components. (1) The heat required to raise $7.5 \times 10^{10} \text{ kg}$ of water from 22 °C to 82 °C ($1.9 \times 10^{16} \text{ J}$). (2) The heat required to raise $1.8 \times 10^{10} \text{ kg}$ of water to the boiling point at the elevation of the lake surface (98 °C) ($0.1 \times 10^{16} \text{ J}$). (3) The heat required to convert $1.8 \times 10^{10} \text{ kg}$ of water to steam at 98 °C ($4.1 \times 10^{16} \text{ J}$); and (4), the heat lost from the surface of the lake to the atmosphere by radiation and convection. The radiative heat-loss can be estimated from the Stefan-Boltzman equation

$$\delta H / \delta t = \sigma \Sigma (T_s^4 - T_o^4) W \text{ m}^{-2}$$

where σ is Stefan's constant, Σ is the emissivity of the water surface and T_s and T_o are the surface and ambient absolute temperatures respectively. Inserting appropriate values for the variables and assuming that the lake reached 82 °C 1 month ($2.5 \times 10^6 \text{ s}$) before 20 November the radiative heat loss is $0.1 \times 10^{16} \text{ J}$. Similarly the heat lost by convection can be estimated from the approximate expression (ref. 4):

$$\delta H / \delta t = 1.52 (T_s - T_o)^{1/3} W \text{ m}^{-2} (\text{°C})^{-1}$$

which gives a convective heat loss of $0.1 \times 10^{16} \text{ J}$. The total

heat supplied to the lake water between the beginning of the eruption and 20 November was therefore at least 6.3×10^{16} J. This value is certainly an underestimate since it excludes heat lost by conduction into the crater walls and by convective transfer to pre-existing groundwater in the crater walls.

The mass of lava erupted up to 20 November was 10^{11} kg. The available thermal energy of the lava includes the enthalpy of melting (latent heat) and the heat lost by the lava in cooling from its eruptive to its final temperature. Since the lava pile was still growing on 20 November it is clear that it retained a fluid core which was probably still at the eruptive temperature of approximately $1,050^\circ\text{C}$ whereas the outer surface of the lava could not have been at a temperature greater than 100°C . There was therefore a carapace of solidified, though perhaps extensively fractured, lava separating the fluid core from the lake water with a temperature difference of 950°C across the carapace. Any physically reasonable heat-transfer mechanism, either by conduction or by circulation of fluids, requires that the temperature gradient across the carapace should be at least quasilinear which implies that the mean temperature of the carapace was the arithmetic mean of the water and lava temperatures. If the mass of lava forming the carapace was M kg, the total amount of heat lost by the lava in solidifying and cooling from $1,050^\circ\text{C}$ to 575°C was

$$H = M[L + 475C]$$

where L is the latent heat of the lava and C is its specific heat capacity. Taking $L = 3 \times 10^5 \text{ J kg}^{-1}$ and $C = 10^3 \text{ J kg}^{-1} (^\circ\text{C})^{-1}$, then

$$H = 7.75 \times 10^5 M \text{ J}$$

Equating the heat lost by the lava to the heat gained by the lake we have

$$M = 8.1 \times 10^{10} \text{ kg}$$

That is, of the lava erupted up to 20 November over 80% had solidified and cooled to a mean temperature 475°C below its eruptive temperature by that date. We emphasise that this is a lower limit, because the heat supplied to the lake water is known to be an underestimate. A previous assessment of the heat budget² did not take into account all the factors considered here and was an even greater underestimate of the volume of cooled lava.

The same pattern continued during the rest of the eruption. When extrusion of lava stopped on 20 March 1972 a total of 2×10^{11} kg of lava had been erupted, and 5×10^{10} kg of water had evaporated. By calculations similar to those above we estimate that about 90% of the lava had solidified when the eruption ceased. This again is a lower limit since we were unable to make accurate estimates of the heat lost by radiation directly from the lava to the atmosphere after it emerged from the lake. These observations therefore make it clear that during the 1971–72 eruption of the Soufriere of St Vincent the lava solidified at about the same rate that it was erupted and that the solidified lava cooled considerably after crystallisation.

During the eruption, large quantities of heat were transferred rapidly from the lava to the lake water. The characteristic dimension of a typical lava cooling unit can be estimated from the observation that the lava was able to lose a significant proportion of its heat content to its surroundings within a time period which was less than 1 month. The thermal time constant τ of a body with characteristic dimension R metres and thermal diffusivity $\kappa \text{ m}^2 \text{ s}^{-1}$ is of order R^2/κ . Putting $\tau = 1$ month ($2.5 \times 10^6 \text{ s}$), $\kappa = 10^{-6} \text{ m}^2 \text{ s}^{-1}$ we estimate that the maximum possible characteristic dimension of the individual cooling units was in the range 1–5 m. This result clearly excludes the possibility that the lava mass was extruded as a viscous dome^{3,4} with a characteristic dimension of order 500 m. There seem to be two possible ways in which the intimate mixing of lava and water necessary to cause the observed rapid heat-flow could have been achieved. The first involves breaking the whole

lava pile into individual blocks with diameters less than 5 m. This possibility can be excluded simply on the grounds of visual observations at the time of eruption¹. There were indeed rock avalanches during the later stages of the eruption but these involve only a very small proportion of the erupted mass. The second possibility, which is supported by the visual observations, is that the lava pile grew by the successive extrusion of overlapping flow-units, each with a characteristic dimension (which in the case of flow is its thickness) of order 1–5 m.

The combined field observations¹ and calorimetric evidence show that the 1971–72 eruption was a quiet extrusion of a lava flow. The gross morphologic form of the lava mass was controlled by the shape of the container (crater) and the cooling effect of the surrounding lake water, and not by the viscosity of the lava. Other features of the eruption, particularly the lack of associated seismicity, the absence of explosions and the composition of the lava suggest that the viscosity of the magma was low and the results presented here show that the gross morphology of the lava pile is consistent with this conclusion.

This eruption marks the first documented extrusion of a lava flow in the Lesser Antilles island arc. Previous events of extrusion of minor lava masses within the Soufriere crater lake are, however, indicated by very sketchy historic accounts¹, suggesting episodes of minor lava extrusion at intervals between the major explosive eruptions of this volcano. The fact that the Soufriere is capable of quiet lava flow eruptions as well as violent explosive ones must be considered in any theory of its eruptive mechanism.

Circular structures of large scale and great age on the Earth's surface

THE Earth's surface exhibits faint circular patterns which have not been described before. These circles are characterised by near perfection of outline, by the presence of topographic highs (rims) along parts of their circumferences, by their generally large scale (diameters of from under 7 km up to approximately 700 km in the areas examined), and by their definition in various geological environments, in many rock types, and in rocks of all ages. Many of the circles are intermittent in places along their rims but about 55% of the approximately 1,170 definite circles observed to date can be visually traced around an entire 360° of arc. The circles are further characterised by the presence of fracturing and brecciation along parts of their rims and by the extraordinary control they place on regional geology in general and on ore mineralisation in particular.

To date, circles of this nature have been observed clearly in several areas with ancient continental crust at depth: the western United States, northernmost Mexico, the Appalachians, Alaska and the Yukon. Their existence is also strongly indicated in Madagascar and Corsica. No other areas have been examined. The circles are visible on displays which were produced from commercially available raised plastic relief maps

Fig. 1 Portion of Arizona at a scale of 1 : 1,000,000 produced by the method outlined in the text. The original relief maps were sprayed white and had twofold vertical exaggeration. The test area is bounded by thick latitude and longitude lines and the extra areas to the west and south are included to facilitate viewing of some of the circles.

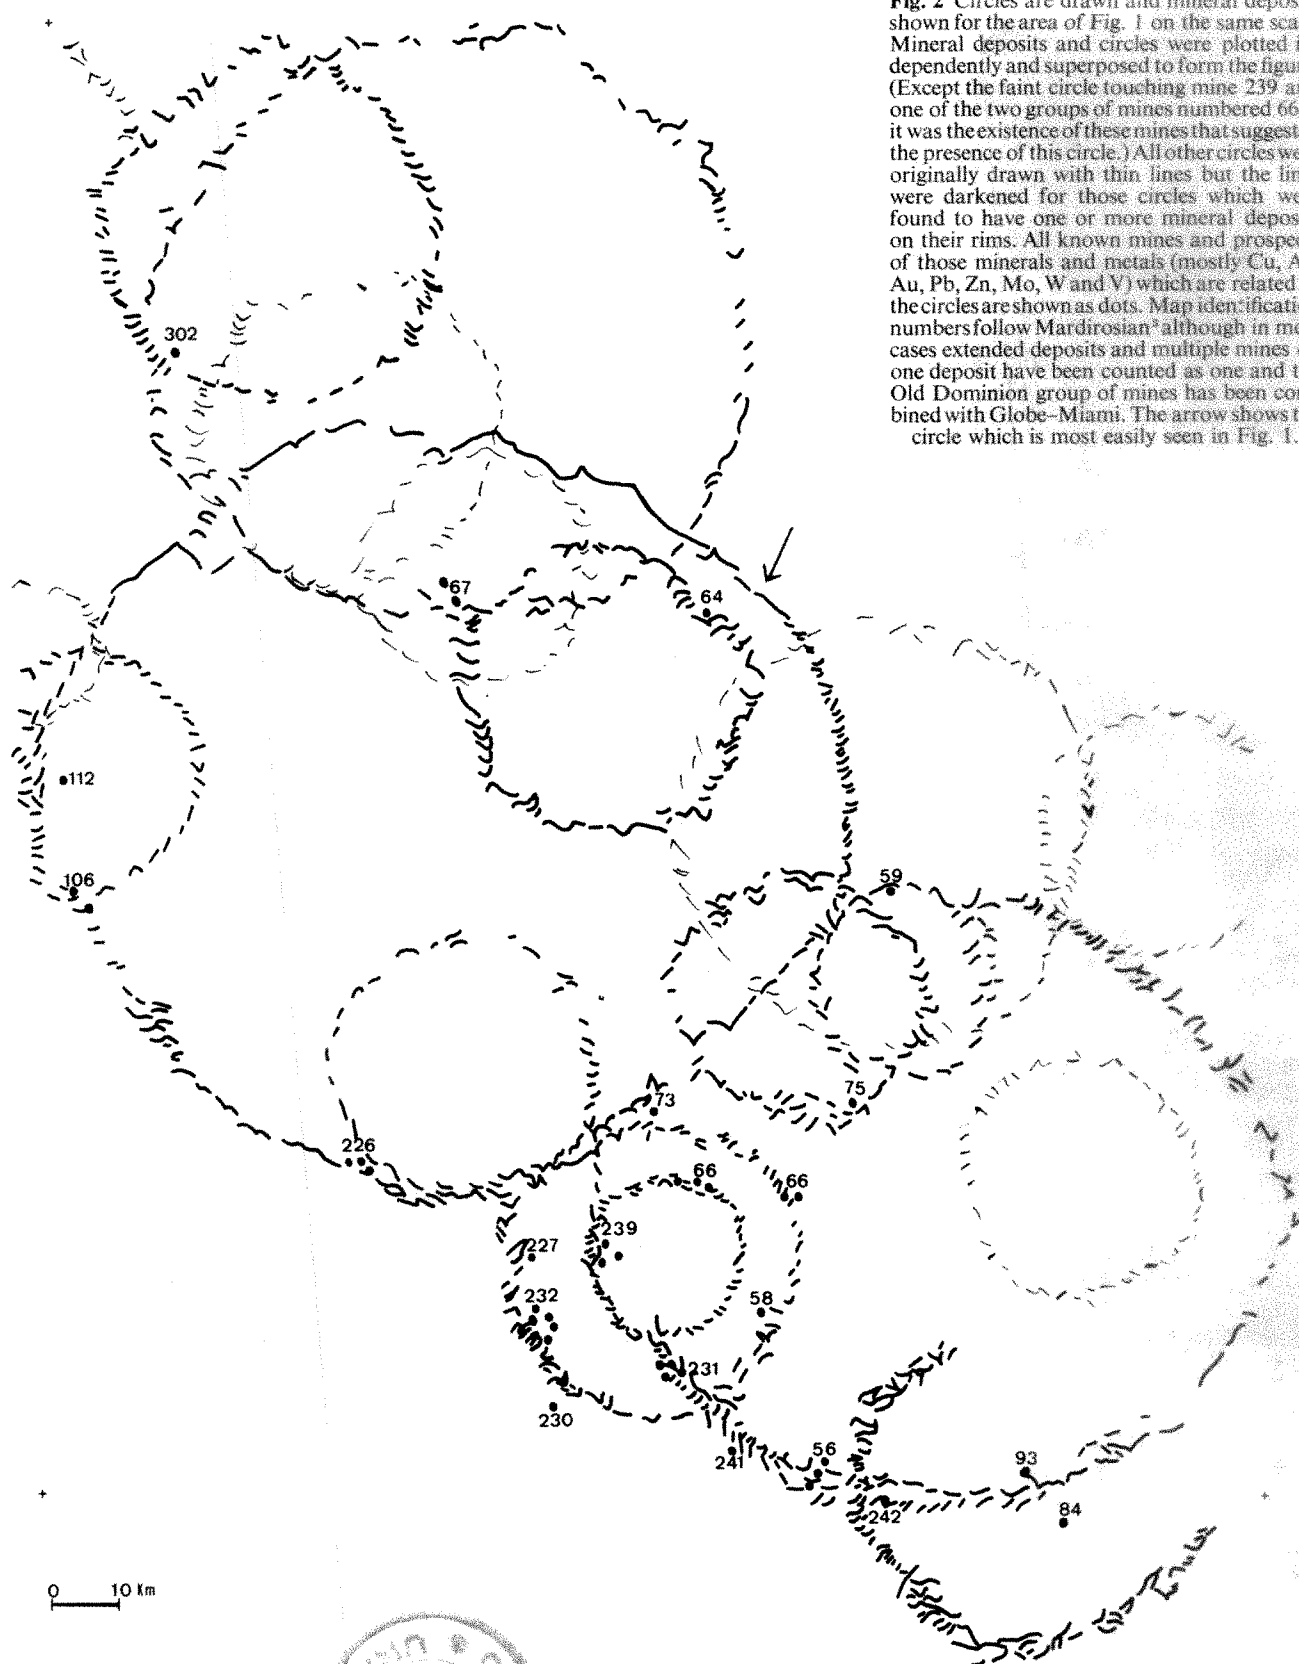

Fig. 2 Circles are drawn and mineral deposits shown for the area of Fig. 1 on the same scale. Mineral deposits and circles were plotted independently and superposed to form the figure. (Except the faint circle touching mine 239 and one of the two groups of mines numbered 66—it was the existence of these mines that suggested the presence of this circle.) All other circles were originally drawn with thin lines but the lines were darkened for those circles which were found to have one or more mineral deposits on their rims. All known mines and prospects of those minerals and metals (mostly Cu, Ag, Au, Pb, Zn, Mo, W and V) which are related to the circles are shown as dots. Map identification numbers follow Mardirosian² although in most cases extended deposits and multiple mines on one deposit have been counted as one and the Old Dominion group of mines has been combined with Globe-Miami. The arrow shows the circle which is most easily seen in Fig. 1.

Table 1 Lode occurrences in the Arizona test area of those metals and minerals whose emplacement is controlled by the circles

District, mine, area or deposit	Principal commodities

Squaw Peak (302)	Cu, Mo

The data shown are taken from Mardirosian³.

*The figures in parentheses are reference numbers taken from ref. 3 and are also used in Fig. 2.

†The Old Dominion mines have been added and are grouped with Globe-Miami.

with a 1 : 250,000 scale and a two- or threefold vertical exaggeration. These were illuminated at a low angle by a parallel light source and photographed individually. Photographs of adjacent maps were joined to give regional coverage^{1,2}. Figure 1 is an example of such a display and covers a part of Arizona.

The area shown in Fig. 1, extending from 33° to 35°N and from 110° to 112°W, covers several mining districts and was selected as a test area in which to examine the relationship between circles and mineralisation. Known mineralisation in this area includes 24 mappable occurrences or deposits of copper, silver, gold (other than alluvial), molybdenum, vanadium, tungsten, zinc, lead (other than lead occurring with alluvial gold), iron (where associated with other metals), manganese (where associated with other metals), serpentinised limestone, and turquoise. Most of the deposits are polymetallic and four are major porphyry deposits (Globe-Miami-Old Dominion, Magma-Silver King-Superior, Ray-Kelvin, Christmas-Troy-Dripping Springs-Hayden). Table 1 gives additional details. Nineteen circles were located within or partly within this test area and forty measurements of the apparent rim widths of these circles gave an average value of 2.1 km.

Using this rim width, it was found that twelve of the nineteen circles had at least one known mineral deposit along their rims and that all 24 mineral occurrences or deposits of the types listed above fell 'on' or 'very close' to a circular rim. These two terms correspond to the two highest ratings in the five point semi-quantitative scoring system used. Most of the 24 deposits were in the 9% of the total area which was classified as 'on' a rim (see Fig. 2).

The circles are not easy to see, even on the original photographs, and it is possible that a few of the faintest circles have no objective reality. There is, however, a positive correlation between degree of visibility and mineralisation. The five most visible circles have 16 out of the 24 mines or deposits associated with them. The five next most visible circles have 11 mines or deposits on or near them, 7 of which are also on or near one of the most visible circles. The nine least visible circles have only 3

deposits on them, all of which are also on or near a more readily visible circle. The degrees of visibility were assigned by J. B. Southard of the Massachusetts Institute of Technology without reference to the presence of mineralisation. One additional faint circle with mineralisation was found after the assignment of the degrees of visibility, and numerous other faint or doubtful circles were noticed subsequently. The portion of the test area covered by rims is increased from 9% to 42% if all of these are accepted.

Occurrences in the Arizona test area of asbestos, barite and iron (when not associated with other metals) also seem to bear some relationship to the circles. There was no correlation between the circular rims and the locations of deposits of uranium, manganese (in monometallic ores), perlite, placer gold, mercury, gypsum, sand and gravel, sandstone, limestone, peridot, quartz crystal, amethyst, jasper and onyx marble. No other occurrences of economic minerals or stones are reported from the area with the exception of fossil fuels³. A brief survey of circular rims found in the Butte, Montana area also showed a strong correlation with mineralisation, so the striking results from Arizona are not unique.

The correlation of mineralisation with the circles stands on its own and does not depend on the acceptance of any particular theory as to how the circles came into existence.

Individual circles exhibit different degrees of visibility. In general, a circle that is readily visible along one portion of its circumference will be readily visible over the whole circumference, and a faint circle will be uniformly faint. The great majority of circles are indeed indistinct, and there is a real problem in reproducing the same circles in different viewings of the photomaps. Larger circles are easier to see than the smaller circles and a positive correlation between circle size and presence of mineralisation is suggested. This may have an upper limit, however. In this study no major mines were noted on circles larger than 150 km in diameter. Much larger circles may also exist. A circular feature of generally similar appearance and a 2,200-km diameter seems to encircle the southern end of Africa, passing through the watershed area of central Angola, the Limpopo Valley region, the offshore edges of the Mozambique and Agulhas Plateaus, various seamounts and the Walvis Ridge.

Intersections of two circles seem to have a somewhat enhanced chance of being mineralised and thus the identification of the fainter circles may prove important after all. In a few cases, the most notable of which is the Bingham copper mine in Utah, mineralisation was found at the intersection of a circle and an obvious linear feature.

The centres of the circles seem to fall in a northwesterly trending pattern in Arizona and in a northeasterly trending pattern in the Appalachians, in both cases forming elongated clusters parallel or nearly parallel to the regional geological trends. Circles are much more abundant in mountainous areas than in the adjacent plains in many regions.

The positions of many towns, roads, railroads, rivers, lakes and reservoirs seem to be related to circles and this is probably a natural consequence of the fact that the circles are defined by topographic criteria.

There is little or no correlation between circles seen on the displays used in this study with circles seen on ERTS photography.

A final observation offers an essentially independent verification of the features discussed here: when transparent overlays with circles plotted on them are reproduced at the correct scales and placed over geological maps of the corresponding areas, the various colours representing different rock types fall into new patterns which, although previously unperceived, either on the maps or in the field, are real and require interpretation. Figure 2 can be enlarged to make a suitable overlay for the Geological Map of Arizona⁴.

The circles can be interpreted as having been formed by the impacts of meteorites during the most recent major bombardment of the Earth. At the time of this bombardment, which

by analogy with the moon, was a discrete episode approximately 4,000 Myr ago, the Earth already had a brittle crust. Estimates of the thickness of that crust vary greatly. The Earth today is brittle down to a depth of at least 2.5–4 km; below this it is ductile. Impacts can cause major fracturing through to the brittle/ductile transition depth and the resulting scars may never heal completely due to a combination of several mechanisms. For instance, as the impact site is eroded away, the ductile subbasement will rise and become brittle with decreasing pressure, and the circular scars will be propagated downwards to the new brittle–ductile boundary. Similarly, movements in the fractured zones can be generated upwards to bequeath the circular patterns to overlying sediments or igneous sequences^{5,6}. A history of this nature seems capable of accounting for the preservation of some of the circular scars throughout geological time. The present-day fracture patterns may thus be inheritors or descendants of the original impact craters rather than direct remnants of the craters themselves. The circles differ from previously described astroblemes and the usual criteria of shock metamorphism have not been used for their recognition.

The process of sequential inheritance, by which the geological structures remain after the rocks in which they were formed are gone, is proposed as the mechanism which permits 4,000-Myr-old circular structures to exist in profusion on a planetary surface which holds virtually no rocks thought to be of such antiquity. The geological structures remain after the rocks in which they are formed are gone—an analogy to the smile of the 'Cheshire Cat' comes to mind. Alternative hypotheses avoid this problem but give rise to others.

(1) If the circles are interpreted as artefacts of the map maker, the correlation with mineralisation is unexplainable.

(2) Although some of the circles may be modified calderas (there is evidence suggesting that some Tertiary and Quaternary calderas may have inherited and taken over pre-existing circular sites), the circular scars have a systematically higher degree of circularity than is typical of recognised calderas, and caldera complexes and their metamorphosed equivalents would have to be very much more widespread than present geological maps indicate.

(3) If the circles have been generated from below at various times as, say, super ring-dikes, or their extrusive counterparts, why are their rocks not generally recognised as such and mapped appropriately? In addition, the apparent absence of super ring-dikes in fresher states of preservation would seem to go against the principle of uniformity. The super ring-dike explanation is also difficult to reconcile with the observation that there are few circles smaller than 7 km in diameter and none under 5 km. On the other hand, the small scars caused by impacts which did not break through to the brittle–ductile boundary would have healed over completely in time. Partially healed astroblemes might exhibit features which are, nevertheless, similar in appearance to those of large ring dikes.

Difficult questions remain even if the impact scar origin for the circles is accepted. For instance, the trends which parallel the regional geology in Arizona and the Appalachians have no clear interpretation, nor does the observation that the circles are found in greater numbers in the mountains than in the surrounding plains. Two useful speculations concerning these observations are: first, that the presence of the circular structures permitted or even caused the mountains to form where they did, or, alternatively, that the forces that formed the mountains also reopened the old scars and, second, that the limited sensitivity of the map making or photographic techniques used hinders the identification of circles in regions of low relief.

Geological activity after the formation of the circular features might have prevented their complete healing over and thus: (1) permitted the intrusions of the igneous bodies which are partly responsible for the topography of the rims, (2) permitted the introduction of mineralising fluids from below, (3) permitted the introduction of descending and oxidising surface waters from above, and (4) maintained the circular patterns on the Earth's surface.

Two main characteristics of 'porphyry' copper deposits are association with an intrusive body and, in almost all cases, supergene enrichment of the ore zone. A third characteristic is dependence on intense fracturing whose nature has not been satisfactorily explained previously^{7,8} despite the observation by Godwin in 1973 that "some breccias and adjacent rocks in the vicinity of porphyry deposits . . . have features that seem indicative of shock metamorphism"⁹. This study has shown that a fourth characteristic of porphyry deposits in the Arizona test area and elsewhere is that they are confined to circular rims. All these characteristics can be explained as consequences of an impact-scar site of formation.

If the circles are formed by impacts, they will be surface expressions of forms which, due to geometrical constraints, are generally cylindrical or perhaps somewhat conical. These are most probably essential elements of the "deeply penetrating fundamental 'plumbing' systems" which Jerome and Cook¹⁰ and others believe exert a controlling influence on the concentration of metals. For the case of the porphyry type deposits, it is evident that the circular patterns and their extensions in depth did influence the movements of various fluids, hot, cold, rising, descending, viscous, non-viscous, recent and ancient, and this suggests why other types of deposits which are formed partly through the action of thermal waters (gold-bearing quartz veins, for instance) should be preferentially located on the circular rims. A logical extension of this concept and some fragmentary evidence indicate that the scar structures also affect the distribution of other fluids, groundwater, gas and oil.

I thank Renée Lecomte for preparing the manuscript, Sylvie Salade for plotting the circles, Ruth L. Saul and Janice A. Glaholm for editing, and Professors John B. Southard (Massachusetts Institute of Technology) and Gerald J. Wasserburg (California Institute of Technology) for useful comments.

Palaeolithic–Neolithic seed remains at Franchthi Cave, Greece

FRANCHTHI Cave is located in a limestone headland on the south-west coast of the southern Argolid, Greece. In excavations since 1967 (performed under the direction of Prof. Thomas W. Jacobsen, Indiana University) an almost continuous sequence from the Upper Palaeolithic ~20,000 BC to the Final Neolithic, around 3000 BC, has been uncovered¹. After six excavation seasons, eight trenches have been opened up inside the cave, as well as eight trenches outside the mouth of the cave and along the beach about 50 m below. Owing to the proximity of the deposits to the modern shore line and to the soil surface, no carbonised material has been recovered from these beach deposits. This is unfortunate because the earliest Neolithic on the site has been found in this area. Concentrated water sieving of the trenches inside the cave has recovered large quantities of carbonised botanical material. Most important among these remains has been the discovery of wild oats and wild barley in levels dated to about 10,000 BC, earlier than any botanical remains as yet found in Greece or the Aegean area.

Table 1 Dimensions of *Hordeum spontaneum*

Minimum	4.2	2.1	1.0	164	47
Maximum	7.5	3.6	2.1	250	90

*After van Zeist and Casparie⁵.

Inside the cave, the two largest and deepest trenches, F/A and H/H-1 quadrants A and B, have been systematically water sieved for the recovery of botanical and other environmental material. Because of the fresh water springs running into Koilada Bay below the mouth of the cave, it was possible to use nearly fresh water rather than salt water for this sieving process. A dam was built and a large hose inserted at the mouth of one of the springs. Water from the spring was then pumped up into two 1 m² storage tanks installed up the slope from the dock on which the smaller sieving tanks were placed. The earth was dumped slowly into these smaller tanks which contained a nylon net mesh of ~ 1.5 mm. The water flowing into the bottom of the tank separated the soil from the rest of the material. The carbonised remains, as well as small snail shells and bones were floated off into another nylon net which was then set on specially built racks indoors to dry.

To date this flot from the south half of F/A and one quadrant of H/H-1 (A) has been sorted, giving a nearly complete sequence from the Upper Palaeolithic (P2233-21,480 ± 350 yr bp; ~ 20,000 bc (all ¹⁴C dates are calibrated with a 5,568 yr half life) through the 'Mesolithic' (a tentative designation for the material from levels dating between 8300 bc to 6000 bc) and Neolithic to the Final Neolithic (P1660-5,261 ± 64 yr bp; ~ 3000 bc). A preliminary identification has been given to most of the botanical remains from this sequence, but measurements have not yet been made on most of the seeds and positive identification for many of the species must wait for further research.

The lowest levels dating from around 20,000 bc up to 11,000 bc contain only species of the Boraginaceae family, namely *Lithospermum arvense* L., *Alkanna* cf. *orientalis* (L.) Boiss., and *Anchusa* sp. A small percentage of these have been burnt, but the majority are in a 'fresh' state. The vast numbers of these species, as many as 2,000 *Alkanna* sp. in one unit, are difficult to explain. There are several possibilities, such as the use of the plant for bedding or fuel, or the use of the root as a dye. Perhaps the seeds were not brought into the cave by man but are the result of rodent or bird activity. There are many bird bones in these levels; this may support the suggestion that these stony seeds were used as 'crop stones' by the birds (S. Payne, personal communication). Further study of the faunal and cultural material from the Upper Palaeolithic may help to solve this problem.

In deposits dated to 11,000 bc lentils were recovered. These are an extremely small species (about 2 mm diameter, but their condition and the present lack of comparative material, will not allow a positive identification to the species level. According to Zohary, both *Lens nigricans* (Bieb.) Godr. (*Ervum nigricans* Bieb.) and *L. ervoides* (Brign.) Grande (*L. lentacula* (Schreb.) Alef.) are small-seeded lentils which are typical Mediterranean elements today. *L. orientalis* (Boiss.) Hand-Mazz. has also been reported from Greece² and is more closely

related to the cultivated *L. culinaris* Medik (*L. esculenta* Moench) than the other two species³. These early lentils at Franchthi may be one of the more common Mediterranean species and are unrelated to the cultivated lentils which appear in the Neolithic deposits on this site. The possibility of their being *L. orientalis*, however, which were collected through the Upper Palaeolithic and Mesolithic and developed into the cultivated variety in the Neolithic must also be considered.

Also occurring in the Palaeolithic deposits at about the same time as the lentils are a species of vetch (*Vicia* sp.). These are small round seeds (2.5-3 mm diameter) which, again, have not been identified to the species level as the hilum is missing from all those otherwise complete enough to measure. The positive identification of the vetches from the cave will be left until it is possible to compare the samples with an adequate modern collection.

At the same time that lentils and vetches begin to appear in the Upper Palaeolithic levels, pistachio (*Pistacia* sp.) and almonds (*Prunus amygdalus* Batsch.) appear. These two species occur together throughout the entire sequence to the Final Neolithic. The *Pistacia* sp. has previously been identified as *P. atlantica* Desf⁴, but the closer examination of the seeds of *P. terebinthus* L. and *P. lentiscus* L. may indicate their presence. Complete measurements of the Franchthi material are needed before any definite species can be assigned. The asymmetry of the Franchthi nutlets suggests that these may be closer to the *lentiscus* than the *atlantica* form.

The almonds have been identified as *Prunus amygdalus* Batsch., but as there is only one whole almond in the entire sequence, it is difficult to be certain of the identification. The whole specimen is 16.5 mm long and 11.8 mm wide. The surface is slightly pitted and grooved and the keel is not prominent.

In levels dated to around 10,500 bc (P1827-12,543 ± 176 yr bp) two grains of oats (*Avena* sp.) and one of barley (*Hordeum* cf. *spontaneum* C. Koch.) have been identified. Neither species occurs again, however, until about 9000 bc in trench H/H-1 A (Palaeolithic) and 7000 bc in trench F/A (Mesolithic), from which points they become major components of the botanical assemblage through the Mesolithic.

There is a problem with the identification of the barley grains in that they are broken and so badly preserved that it is impossible to obtain complete measurements. They have been tentatively identified as *H. cf. spontaneum* on the basis of their similarity to the illustrations of the wild barley reported from the site of Tell Mureybit in Northern Syria⁵, and with modern *H. spontaneum* in the comparative seed collection at the University of Southampton. The grains from Franchthi, however, are larger than those from Mureybit as seen in a comparison of the dimensions (Table 1). Of those grains well enough preserved to measure, it is possible to describe them in much the same terms as used for the Mureybit grain. The dorsal side is longitudinally straight or slightly curved due to puffing during carbonisation. The ventral side is straight or barely convex. In every case one or both ends of the grain is broken off, but they are generally broader at the upper end, tapering toward the lower (radicle) end.

The positive identification of these grains is a crucial factor in the question of early domestication at Franchthi. If the Mesolithic barley is, in fact, a domesticated form it would be the earliest found so far in Greece. Should it prove to be a wild species, however, it raises the question as to whether it is the progenitor of the cultivated barley found in the Neolithic levels at Franchthi. In either case the material will prove to be of great importance in the study of the origins of agriculture in this area.

The oats (*Avena* sp.) will probably not be identified further as there are no lemma bases preserved in the deposits. The grains are very small, the average length being 4.2 mm for the 12 grains so far measured (Table 2). They are spindle shaped, tapering at both ends to a point. On a few of the better preserved grains the hairs are still visible. The number of different species of wild oats in Greece, and the possibility of these being

Table 2 Dimensions of *Avena* sp. from Franchthi Cave

	Length	Breadth	Thickness	L:B	T:B
Average	4.20	1.35	1.13	314	85

Fig. 1 Botanical remains found in Franchthi Cave.

secondary grains make a definite identification impossible.

Around 8000 bc (P2231–10,260 ± 110 yr bp) in trench F/A the Boraginaceae decrease substantially down to only a few seeds in each unit, and the *Pistacia* sp. increase greatly, becoming the predominant species in the Mesolithic. At one point, however, dated to about 7000 or 6500 bc, there may have been a redeposition of earlier soils as the soil matrix itself is of the reddish, clayey Palaeolithic type and there are vast quantities of *Lithospermum arvense* in these units. At the same time there is a decrease in all other botanical finds in this trench. Further study of the stratigraphy in this area is necessary before we can determine exactly what has happened at this point in the cave's occupation.

Also in the Mesolithic, beginning around 7300 bc (P2230–9,280 ± 110 yr bp), wild pear (*Pyrus amygdaliformis* Vill.) begins to appear. Both whole carbonised fruits and the seeds have been preserved in these very rich deposits. In addition to the lentils and vetches, peas (*Pisum* sp.) have been identified from two Mesolithic levels¹. As yet, no additional finds of this legume have been recovered from these trenches. There are large legumes from these Mesolithic levels which resemble more closely a *Lathyrus* sp., but positive identification must await further study.

The next substantial change in the sequence comes at about 6000 bc (P2095–7,981 ± 105 yr b.p.) with the absence of oats and the first appearance of *Triticum dicoccum* Schubl., cultivated emmer wheat. The change is sudden and complete in trench F/A, occurring through a depth of about 15 cm of earth, and suggests that there may have been a stratigraphic break or a lack of occupation, at least in this part of the cave at this time. *Hordeum distichum* L., cultivated two-row hulled barley, appears shortly after the *Triticum*, both species begin to occur in steadily increasing numbers in levels dated to around

5000 bc. There is also a change in the lentil at this point and those now occurring are the larger, cultivated variety *Lens culinaris* Medik. The vetch also seems to have changed, and the species represented has been tentatively identified as *Vicia ervilia* (L.) Willd. (= *Ervum ervilia* L.). The *Pisum* sp. which had been present in the Mesolithic has not been found in the Neolithic deposits so far examined. Pistachio and almond still occur and very small numbers of Boraginaceae are present in scattered units up to the Final Neolithic.

There is no major change in the species represented throughout the Neolithic with the exception of the appearance of *Triticum monococcum* L. at about 4500 bc in the upper Middle Neolithic levels. This species continues to occur in very small numbers in the late and Final Neolithic as well. Several wild grape pips have been found in the late and Final Neolithic levels and have been attributed to the species *Vitis sylvestris* L.

The extensive water sieving operation (Fig. 1) at Franchthi Cave has therefore, produced, a sequence of botanical material from the Upper Palaeolithic (~ 20,000 bc) to the Final Neolithic (~ 3000 bc). In the Upper Palaeolithic wild species of lentils, vetches, pistachios, almonds, oats and barley were collected. These species remain the primary botanical resources recovered from the cave through the Mesolithic to the Neolithic. In addition, wild pear and peas have been identified from the Mesolithic levels.

There seems to be an abrupt change in these resources around 6000 bc when the wild oats and barley and the wild pear disappear from the botanical material so far examined and the cultivated varieties of emmer wheat, hulled two-row barley, and lentils are found. Cultivated einkorn wheat is present in small amounts from the later Middle Neolithic levels, and wild grape first appears in the Late Neolithic.

The great importance of the Franchthi material is that it

helps to fill a void in our knowledge of pre-Neolithic subsistence in Greece. No other site in this area of the Eastern Mediterranean has yielded botanical material dated to the periods before agriculture had become established. Not only can the Franchthi material answer some of the questions concerning the gathering economy preceding agriculture, but it may also be of primary importance in establishing whether or not agriculture was incipient or introduced to Greece. It has long been felt that the knowledge of cultivation had been brought to Greece from the Near Eastern 'centres'. With the appearance of both earlier, wild forms and later, cultivated forms of certain species at Franchthi Cave, there must be a rethinking of this problem of the origins of agriculture.

Although this is only a preliminary report of the Franchthi botanical material it is hoped that further work will confirm some of the tentative statements and that it will help us to understand the crucial period of subsistence change from plant collecting to plant cultivation.

These excavations were performed under the direction of Professor Thomas W. Jacobsen, Indiana University, as part of the Argolid Exploration Project cosponsored by the University of Pennsylvania and Indiana University¹.

Lipid sacs as a buoyancy adaptation in an Antarctic fish

THE Notothenioidei, the dominant perciform suborder of Antarctic fishes, is a predominantly benthic group of about 75 species¹. They lack a swim bladder, a feature consistent with their mode of life on the bottom of the sea¹. Therefore few of them have been able to exploit the enormous biomass of planktonic crustaceans (krill) indigenous to the mid-waters of the Antarctic Ocean^{2,3}. One notable exception, however, is the nototheniid *Pleuragramma antarcticum* Boulenger which has invaded this highly productive habitat. Unlike other members of this family, *Pleuragramma* spends its life swimming in the water^{2,4}, at times beneath a cover of sea ice. Although *Pleuragramma* lacks a swim bladder, it has been observed to remain nearly motionless in the water when placed in an aquarium. Furthermore, its slow swimming speed and general body morphology (Fig. 1) appear to preclude the use of forward motion and associated hydrodynamic lift as a mechanism for maintaining position in the water column. In -1.8°C seawater, specimens of *Pleuragramma* weighed between 0.5 and 1% of their weight in air indicating they were almost neutrally buoyant. We report here that this reduction in density results from the accumulation of lipid in intermuscular and subcutaneous sacs, and from a reduction in skeletal ossification.

Pleuragramma were collected by lowering a 2-m² net to a depth of 475 m through a 3-m² hole in the ice at McMurdo Sound, Antarctica (77°54'S, 166°40'E). The net was retrieved at the rate of 60 m min⁻¹.

When freshly caught specimens of *Pleuragramma* were trans-illuminated, translucent sacs (0.5–3.0 mm in diameter) containing lipid were seen between the muscle masses at the bases of the dorsal and anal fins. Gross staining of formal-calcium-fixed specimens with oil red O (ref. 5), a stain for neutral lipids, confirmed the presence of lipid and also revealed the existence of many smaller (0.2–1.5 mm) subcutaneous sacs (Fig. 1)

on the sides of the body. Subcutaneous sacs were also seen in the midventral line between the pelvic girdle and the anterior margin of the anal fin. In cross section the intermuscular sacs were medial to the dorsal and ventral-most subdivisions of the epaxial and hypaxial muscle masses (Fig. 2). In this position they were adjacent to the median septa, pterygiophores and the associated erector and depressor muscles of the fins.

Fig. 1 *Pleuragramma antarcticum* showing distribution of subcutaneous lipid sacs (large black dots) in an adult specimen. Redrawn from Boulenger¹⁵. Arrows indicate the plane of Fig. 2.

Examination of histological sections stained with haematoxylin and eosin or picro-ponceau indicated that the lipid was enclosed in delicate connective tissue sacs, true adipose tissue being rare in fishes⁶.

For analysis, 1 ml of lipid was withdrawn from the intermuscular and subcutaneous sacs of a 30-g specimen. Thin-layer chromatography revealed that the lipid was entirely triglyceride. Extraction and analysis of the total lipid content of the trunk musculature showed that 39% of the dry muscle mass was lipid, with 75% of that being triglyceride (personal communication from P. W. Williams). The methyl esters of the triglyceride fatty acids were prepared⁷ and quantified by gas-liquid chromatography on a column of 10% SP 2340 resin on Chromasorb WAW. The fatty acid composition of the total triglyceride isolated from the muscle was similar to that of the triglyceride present in the sacs.

The density of triglyceride is approximately 0.93 at 0°C. This large amount of extracellular lipid must significantly reduce the density of *Pleuragramma* and would appear to be involved in buoyancy regulation, as is the case with other mid-water fishes which lack swim bladders⁸. The localisation of the lipid in preserved specimens is consistent with this hypothesis; the sacs were largest and most numerous near the centre of gravity of the fish.

Accumulation of lipid was not the only mechanism observed to play a part in density reduction in *Pleuragramma*. Specimens

Fig. 2 Cross section of *P. antarcticum* showing location of intermuscular lipid sacs. Hatching, red muscle fibres of lateralis superficialis; stippling, epaxial and hypaxial muscles, erector and depressor muscles of fins; solid black, bone (pterygiophores, vertebral collar and trabeculae); LS, intermuscular lipid sacs; NV, notochordal vesicles (do not contain lipid). Bony tissue in the vertebrae is confined to a thin peripheral collar buttressed by longitudinal trabeculae running the length of the column. These appear as small, lateral projections in this cross section. Notochordal material fills the entire vertebral body and is continuous throughout the extent of the column. The dorsal and ventral median septa connect the tips of the neural and haemal spines to the pterygiophores.

cleared and stained with alizarin red S⁹ had reduced and poorly ossified skeletons compared with other Antarctic nototheniids. For example, the vertebrae were not amphicelous, but merely a thin collar of bone surrounding, and barely constricting, a large core of gelatinous material (Fig. 2), probably representing a persistent notochord. Furthermore, neural and haemal arches and spines were reduced, and ribs were very small. In addition, the scales were thin and weakly mineralised. These observations were further supported by ashing the bones for 10 h at 450 °C. The ashed skeleton of *Pleuragramma* constituted only 0.3–0.5% of the total body weight compared with 0.9% for a closely related but less actively swimming species, *Trematomus borchgrevinki*. In most fishes the ash content of the skeleton is about 2% of the total body weight¹⁰.

It has been suggested before that lipid deposits in liver^{11,12}, bone^{13,14}, integument¹⁴ and muscle¹⁴ play a role in buoyancy regulation. In such cases, however, the precise role of lipids is obscured by the fact that these organs are complicated structures with primary functions unrelated to buoyancy control. In *Pleuragramma* the utility of the lipid sacs in buoyancy regulation can be more easily assessed for two reasons. First, because they are distinct and isolated structures, the only other function attributable to the sacs would be lipid storage before metabolic utilisation. This, however, seems unlikely because the lipid is not in fat cells. Second, there seemed to be an obvious correlation between the appearance of lipid sacs and the degree of skeletal ossification. That is, in small specimens (less than 44 mm) with very slight ossification of the skeleton, subcutaneous and intermuscular lipid sacs were not present. In somewhat larger (45–60 mm) specimens exhibiting some ossification, a moderate number of sacs were present. In large adults showing considerable skeletal ossification, the sacs were extensively developed. The lipid accumulating with increase in size of the fish should serve to offset increasing density resulting from ossification.

Thus it seems that both intermuscular and subcutaneous lipid accumulation and a reduction in skeletal ossification have evolved as specialisations to reduce density in *Pleuragramma*, a pelagic Antarctic fish without a swim bladder. These adaptations enable this fish to maintain the neutral buoyancy necessary for swimming and feeding in the midwaters of the Antarctic Ocean—an ecological niche underutilised by fishes.

We thank Ed Osada for helping net the *Pleuragramma*. This research was supported by the USNSF.

Equalisation of prey numbers by migratory shorebirds

STUDIES of the effects of predators on prey diversity have usually focused on patterns of predation that do not by themselves increase diversity. For example, size-selective fish decrease diversity by driving large bodied zooplankton to local extinction¹. Size-selective predators can maintain a diversity of species only if large bodied prey hold some advantage over smaller prey, such as the difference in feeding efficiency hypothesised by Brooks and Dodson (ref. 1 and see ref. 2 for review). The diversifying effect of nonselective predation on competitors for space in the rocky intertidal zone³ depends on the presence of differences among competitors in time of settlement during the year. In contrast, selective removal of common prey tends to reverse any numerical advantage gained by one species over another. Thus it is of interest to see whether numerically selective predators increase diversity by equalising prey numbers. The results presented here show that general predators in fact repeatedly equalise the relative abundance of prey species and hence tend to stabilise prey communities.

Migratory shorebirds are flexible predators^{4, 5} that attain considerable numbers in estuaries along the Atlantic coast of North America. Daily counts of shorebirds in the Plymouth, Massachusetts estuary exceeded 5,000 birds from mid-July to mid-August in 1975 and 1976. Most birds belonged to one of four species: sanderling (*Calidrus alba*), semipalmated sandpiper (*Calidrus pusilla*), short-billed dowitcher (*Limnodromus griseus*), and black-bellied plover (*Pluvialis squatarola*).

Each of these species used several foraging techniques at Plymouth, and each showed some degree of habitat selection. Numerical selectivity was evident from examination of crops and gizzards, which generally contained the two or three commonest prey species in the area where the bird had been foraging before collection. Large and abundant invertebrates (*Clymenella torquata*, *Scoloplos robustus*, *Nereis virens*, *N. arenaceodonta*, *Tellina agilis*, *Crangon septemspinosa*, *Acanthohaustorius millsi*, *Trichophoxus epistomus*) were well represented in shorebird diets. Numerical dominants of smaller size (spionid polychaetes, *Gemma gemma*, *Hydrobia (totteni)*, *Protohaustorius deichmannae*) were under-represented relative to their abundance on the flats. Both prey size and prey number seem to be important in the selection of prey by shorebirds⁶.

Invertebrate mortality was estimated by counting the organisms in 20 core samples taken at each of 13 representative sites in July, as birds began increasing in number, and comparing this with the count of organisms at the same sites in September, after most shorebirds had departed. September samples were located within a metre or two of July samples to reduce the effect of a patchy spatial distribution on estimates of invertebrate loss. The sampling procedure itself did not lower invertebrate density, based on the lack of a significant difference between two rounds of sampling at one site on a day in September. All cores were 10 cm in diameter and 10 cm deep. Cores were washed on a 0.5-mm sieve and the organisms visible by eye were counted and recorded in the field. This procedure captures at least 90% of the organisms greater than 2 mm, based on re-examination of samples in the laboratory. The effect of juvenile recruitment on estimates of invertebrate mortality was controlled by recording the size of organisms with sufficient accuracy to distinguish 0-yr class from older animals.

Exclosure experiments in 1975 and 1976 showed that losses between July and September were due to predation. Each exclosure was 1 m on a side, 10 cm high, and made of 14-mm mesh wire. The number of adult invertebrates inside the cages did not change significantly between July and September ($P > 0.50$), compared with the significant declines immediately outside the cages during the same period ($P < 0.05$). Wire cages also exclude horseshoe crabs (*Limulus polyphemus*) and

flatfish (*Pseudopleuronectes americanus*). Flatfish are largely absent from Plymouth Harbour during July and August⁷, when they move offshore into deeper, cooler water⁸. Usage of the study sites by horseshoe crabs did not correspond to invertebrate losses, based on a Spearman rank correlation across the 18 out of 26 0.5-hectare sites where crabs occurred. Mortality at sites used heavily by shorebirds exceeded mortality at less used sites.

Mortality in both years depended on the rank abundance of prey (Table 1). Higher mortality occurred in the initially more abundant prey at a site even though the ranking of individual species in July differed from site to site. Of the numerically dominant macrofauna only *Gemma gemma* did not show substantial losses when abundant. This small (< 4 mm), thick-shelled clam is the commonest species at many sites but it occurs at a low frequency in the gizzards of shorebirds, which suggest that it is relatively unpalatable.

Table 1 Mortality of intertidal invertebrates fed on by migratory shorebirds in Plymouth and Kingston Harbors in 1976

Species rank within sites in July	1	2	3-5	> 5
Average mortality (1-final/initial)	0.84	0.78	0.67	0.36
Average initial density (organisms per 10 cores)	90.9	26.0	26.3	14.1
No. of 0.5 hectare areas	26	26	26	26
No. of different species	6	11	21	32

Mortality is the difference between counts at a site in mid-July and mid-September, divided by the initial count and averaged over sites. All cores were 10 cm in diameter and 10 cm deep. Variation in mortality with frequency was analysed by grouping species according to their rank in July in 10 cores from an area of one-half of a hectare. The change in density within each rank is statistically significant ($P < 0.05$). Changes in mortality between adjacent rankings are all significant at $P < 0.01$, based on a test of the equality of proportions.

Frequency dependent losses resulted in an equalisation of prey numbers during the summer. Equitability ($J' = H'/\ln(s)$, where s is the number of species and H' is the Shannon-Weaver index of diversity⁹), increased significantly from July to September of 1976 ($P < 0.001$), based on a nonparametric Wilcoxon signed ranks test¹⁰. This increase remains significant when the negative association between equitability and collection size has been removed by regression. A similar increase in equitability occurred in 1975. The coefficient of variation¹⁰, another measure of dispersion, decreased significantly in both years.

Shorebirds reduce variation in the relative abundance of their prey by selective removal of numerically dominant species. This would tend to halt the continued expansion of dominant species, since few adult prey escape predation and since these prey reproduce only during the spring and summer. However, differences in palatability make it unlikely that shorebirds could by themselves stabilise an entire community of intertidal invertebrates.

This work was supported in part by contract 14-16-0008-687 from the US Fish and Wildlife Service to the Manomet Bird Observatory. I thank Brian Harrington and the Observatory staff for their help.

Separation of seed development from monocarpic senescence in soybeans

MONOCARPY, a single flowering phase followed by senescence and death, is a widespread phenomenon in seed plants, particularly field crops, whose large monocultures put on a dramatic display during their senescence phase¹⁻⁴. In many, but apparently not all monocarpic species, defruiting or deflowering can prevent or at least delay monocarpic senescence and death¹⁻⁴. For some species such as soybeans, the killing influence has been traced to the developing seeds⁵. The conspicuous correlation between the accumulation of nutrients in the developing fruit and the senescence (or apparent 'exhaustion') of the leaves (Fig. 1) has led to the suggestion that developing fruits cause senescence by diverting or withdrawing needed nutrients or hormones from the leaves and other vegetative parts¹⁻⁴. Here we explore the relationship between nutrient (or hormone) withdrawal or diversion and foliar senescence. Our data indicate that the development (accumulation of dry matter) of the seeds is separable from the senescence response in soybeans, and therefore the seeds may function as more than sinks.

Soybeans (*Glycine max* (L.) Merrill) cv. Anoka were grown in soil as described by Lindoo and Noodén⁶. During the first 4 weeks, the plants were kept in a greenhouse with supplementary light at night and thereafter in environmental control chambers under short (10-h) days. Foliar senescence (yellowing) and fruit development (growth and colour) were measured quantitatively by rapid, non-destructive, visual procedures, which have been checked against the more traditional (but destructive) methods for measuring senescence and fruit development described in detail elsewhere⁶. Fruit development is expressed as fruit maturity index (FMI), which reflects the average state of fruit development based on numerical values 1 (least mature) to 5 (most mature).

Our earlier studies⁶ on soybeans showed the influence of the developing seeds on foliar senescence moves in a restricted pattern within the plant, thereby distinguishing it from the flower-inducing hormone, the movement of which is not as restricted and differs in other ways⁷.

Single axis soybean plants with pods only on the bottom half and foliage only on the top half show greatly reduced foliar senescence compared with unmodified plants and that which occurs is primarily in the leaves nearest to the pods (Fig. 1a). The seed yield of the pod-bearing sections of these plants relative to unmodified plants is not reduced and is, if anything, slightly increased (unpublished data). Subsequent depodding of these 'half-and-half' plants at various stages of fruit development causes an additional reduction in senescence depending on when the pods are removed. Early (up to short day 58) removal of the pods from the bottom half stops foliar senescence, and removal at short day 71 or later does not substantially delay that senescence which does occur.

Figure 1b shows the time course for seed growth (dry weight per plant) and the total seed weight at the depodding. It is important to note that the dry weight of the seeds is nearly maximum (90%) at short day 66 but comparing Fig. 1a with b, it can be seen that depodding, nevertheless, causes an almost total suppression of foliar senescence. These data suggest not only that seed growth can occur without producing foliar senescence, but the senescence is induced mainly during the final phase of seed development when nutrient accumulation is probably complete. The

spatial separation of leaves and pods seems to be important here, for normal plants with leaves subtending the pods do not show this clear distinction between seed growth and senescence when depodded at various stages of seed growth⁵.

When plants are modified to a single leaf and a single pod cluster separated by two nodes, the foliar senescence pattern differs strikingly, depending which is on top, the leaves or the pods (Fig. 2). When the pods are on top, the leaf frequently senesces, whereas it does not when the

Fig. 1 *a*, Time course of seed growth in surgically modified, single-axis soybean plants (leaves only on top half, pods only on bottom half) and the effect of removing the remaining pods at various stages (indicated by A, B, C, and so on) of seed growth. Surgical modification at FMI 1.4 with subsequent removal of pods as they reached the start of pod fill, stage 2. Measurement of senescence, fruit development and FMI are explained in ref. 6. A single node between the top and bottom halves was both depodded and defoliated. *b*, Time course of foliar senescence in single-axis soybeans with leaves only on the top half and pods only on the bottom half. Same plants as in (*a*). Plants designated 'depodded' were completely depodded at FMI 1.4, whereas the 'podded' plants were not modified at all.

pods are below the leaf. This is consistent with our earlier observation that the senescence signal tends to move downward if at all⁵. Neither delayed fruit development nor reduced seed yield can account for the lack of senescence when the single leaf is on top, the time course of fruit maturation in these modified plants is only 4–10 d behind the unmodified control (podded) plants; the yield per node is actually greater in the plants with a single pod cluster than in the unmodified control (Table 1); and the yield per node is the same whether the pod-bearing node is above or below the leaf (Table 1). Complete defoliation at FMI 1.5 reduces the seed yield in these single pod clusters by 80%; most of that seed growth which does occur apparently occurs before defoliation. The single remaining leaf seems to supply required nutrients for the growing seeds and to be subject to whatever nutrient deprivation is created by the seeds.

The experiments shown in Figs 1 and 2 show in different ways that seed development (and therefore nutrient deprivation) can occur without monocarpic senescence.

The reproductive sink size (seed yield) can be controlled by removing all except a defined number of pods from plants at FMI 1.9 (Fig. 3). In this variety and in the conditions used, seed yield (dry weight) was nearly directly proportional to the number of pods per plant; there was no pronounced tendency for seed size to increase in compensation for a reduced number of seeds. The seed nitrogen per plant is likewise proportional to the number of pods, yet foliar senescence is maximum when the number of pods is only about 40% of the maximum. A direct proportionality between sink size and rate of senescence would be expected if monocarpic senescence were caused by nutrient deprivation; in particular, the saturation of senescence induction at very low pod doses is inconsistent with the nutrient deprivation theories.

The possible explanations for the correlative influence of the developing seeds on foliar senescence fall into four

Fig. 2 Time course of foliar senescence and fruit maturation for single-axis plants pruned to one leaf and one pod cluster (separated by three nodes) compared with unmodified plants and depodded plants with all leaves intact. Depodded and defoliated at FMI 1.5 with subsequent removal of pods as they reached stage 2.

Table 1 Seed yields on single-axis soybeans with only one leaf and one pod cluster* or without modification

	Seeds (g dry weight/node) Unmodified plant	Modified plant*
One pod cluster three nodes above a single leaf (or a pod cluster on a comparable node of an unmodified plant)	1.6	1.5
One pod cluster three nodes below a single leaf (or a pod cluster on a comparable node of an unmodified plant)	0.9	1.9

*Same plants as in Fig. 2. Unmodified plants yield about 8.3 g of dry seeds each.

general categories, which have some variations and combinations⁴ but can now be evaluated in the light of the data for soybeans. The first, and least precisely defined, holds that the plants simply have a limited lifespan which runs out about the time the seeds develop. One variant of this hypothesis invokes a limited lifespan for the meristems, the loss of which causes death. Although it may be true that the shoot apical meristems degenerate during flower development thereby limiting vegetative growth (this point needs study in soybeans), depodding of soybeans at an early stage can prolong the life of these plants way beyond normal, possibly indefinitely, even though they undergo little or no vegetative growth. Thus the senescence and death we have observed in conditions favourable for soybean growth is coupled to seed production and not time or meristem degeneration.

The second hypothesis has the developing fruit diverting nutrients (for example, minerals from the roots, photosynthetic assimilate from the leaves) or hormones (cytokinins from the roots) away from the leaves thereby causing their death. Diversion of photosynthetic assimilate from the leaves seems an unlikely cause, for mature or senescent leaves seem to produce more than they need^{10,11}. The diversion hypothesis, particularly the diversion of substances from the roots, is difficult to reconcile with the limited

movement of the senescence 'signal' from the seeds¹. If such a diversion were important, then why does the single pod cluster cause senescence of the single feeder leaf only when the feeder leaf is below the pods and not when above? One would expect the pods to divert substances from the roots more effectively when they are below the leaf. Furthermore, the idea that foliar senescence is triggered by a reduction in the supply of substances produced by the roots, is also countered by the observation that foliar senescence occurs in these plants where the leaf- or pod-to-root ratio is greatly reduced. In addition, the delayed depodding of single-axis plants with pods only on the bottom half and leaves only on the top half suggests that senescence induction by the seeds may occur after most of the seed growth and its concomitant nutrient demands are complete. Note that in order to prolong the life of the plants and to maintain their productivity, expert gardeners take care to remove the fruits from certain varieties of cucumbers and beans after they fill out but before their colour changes (for example, after drain or diversion is completed but before monocarpic senescence is initiated). Finally, the sink size (pod dose or seed yield) does not parallel foliar senescence; the senescence response is saturated at a level far below the maximum level of dry weight and nitrogen accumulation in the seeds.

The third hypothesis involves nutrient drain; the developing fruit are supposed to withdraw nutrients from the leaf to the point of killing them. Indeed, there probably is some exodus of certain nutrients (particularly nitrogen) from senescing leaves¹. The arguments against diversion, however, apply equally well to drain.

The fourth explanation gives the developing fruit or seeds a more active role: production of a substance(s) which travels out to the leaves to cause senescence and ultimately the death of the whole plant.

Although drain and diversion may be involved in the monocarpic senescence of soybeans, it seems unlikely that developing seeds exert such remarkable correlative influences simply by functioning as passive sinks, just as shoot apices do not exert apical dominance solely through nutrient diversion. Such a hormone(s) will, of course, remain hypothetical unless actually isolated and shown to travel from the source (the seeds) to the target (leaves and other parts).

Since monocarpic senescence must have evolved independently in a wide range of groups, it may well be caused by different mechanisms in other species. Indeed, the flowers of male spinach induce monocarpic senescence, even though they do not produce seed². Deflowering retards this senescence, and neither nutrient drain nor diversion seem to be causal. On the other hand, it has been reported that defoliation of cocklebur does not even delay the senescence and death of the whole plant¹².

This study was supported in part by a research grant (416-15-79) from the USDA Cooperative State Research Service under P.L. 98-106. We thank Rohbe Crotz for help in growing the plants during their first 8 weeks and Gary Kahanak for help in completing one set of experiments.

Regulation of RNA synthesis in early germination of isolated wheat (*Triticum aestivum* L.) embryo

THE change from dormancy to germination of seeds requires water and an appropriate temperature. Wheat embryo germination is characterised by an initial increase in fresh weight, followed by a 5-h lag¹. Although RNA synthesis is one of the earliest biologically measurable activities in wheat embryo germination^{2,3}, its mode of regulation has not been established. Reports^{3–6} have suggested that the rate of synthesis does not change during the first 6 h of germination. But no adjustment was made for the specific activities of ribonucleoside triphosphate, UTP. This would have led to a misinterpretation of incorporation data when there was either a change in the concentration of the nucleotide or a difference in the rate of phosphorylation from nucleoside to nucleotide as germination progressed. To investigate further whether there is a change in the rate of RNA synthesis in the germination phase, we have used recently-developed enzyme assays^{7–9} to measure picomole changes in purine pyrimidine ribonucleotide levels. We found a threefold increase in the rate of RNA synthesis of wheat embryos germinated for 40 min–5.5 h. We used the reaction catalysed by uridine 5'-diphosphoglucose pyrophosphorylase to determine the content of UTP. The key step in this analysis is the selective adsorption of the reaction product, UDP-¹⁴C-glucose, on to activated charcoal in the presence of 0.8 M Trizma base⁸.

In a 15-min pulse-labelling experiment, a 5.1-fold increase in the rate of ³H-uridine incorporation into RNA was observed in wheat embryos germinated for 40 min–5.5 h (Table 1, experiment 1). When incorporation data were corrected by adjusting for the specific activity of the UTP, there was a 2.6-fold increase in ³H-uridine incorporation into RNA during the germination phase. When germinating wheat embryos were pulse-labelled for 15 min longer followed by RNA isolation and purification, there was a 2.9-fold increase in 5.5 h (Table 1, experiment 2), similar to the 2.6-fold increase of experiment 1. These results show that the rate of RNA synthesis increases threefold during the period of germination between 40 min and 5.5 h. These results are in contrast to the idea that RNA synthesis does not change during the first 6 h of germination^{3–6}.

The rate of RNA synthesis in the early stage of the germination phase could be limited by either (1) RNA polymerase activity; (2) changes in the template activity of chromatin, or (3) changes in purine and pyrimidine ribonucleoside triphosphate levels. Possibilities (1) and (2) are less likely because the extraction and assay of RNA polymerase does not change for the first 6 h¹¹, and Yoshida and Sasaki¹² reported that the template activity of chromatin is essentially constant for the first 18 h of germination.

There is the following support for possibility (3). To explain the difference in RNA-synthesising capacity between embryos germinated for 40 min and those germinated for 5.5 h, the concentrations of purine and pyrimidine ribonucleoside triphosphates were measured. We found that the cellular level of ATP and GTP increased 60% and 30%, respectively. This minor increase in purine ribonucleoside triphosphates does not corroborate the threefold increase in the rate of RNA synthesis during this period. However, when the pyrimidine ribonucleotide pool was assayed, there was a 400% increase in the level of pyrimidine ribonucleotides during the period between 40 min and 5.5 h of germination (Table 2). The increase of UTP was similar to that of CTP. Thus this large increase in the substrate levels of UTP and CTP could account for

Table 1 Rates of RNA synthesis in wheat embryo during the germination phase

Experiment 1	Labelling periods	
	40–55 min	5.5–5.75 h
5% TCA-insoluble radioactivity	4,130 ± 176 c.p.m.	20,900 ± 377 c.p.m.
Specific activity of UTP	(1)	(5.1)
Adjusted incorporation	1,788 ± 71 c.p.m. nmol ⁻¹	3,511 ± 211 c.p.m. nmol ⁻¹
	(1)	(2.6)
Experiment 2	30–60 min	5.25–5.75 h
RNA fraction	20,410 ± 1,160 c.p.m.	115,040 ± 5,640 c.p.m.
Adjusted incorporation	(1)	(5.6)
	(1)	(2.9)

To prepare the trichloroacetic acid (TCA)—insoluble extract, isolated wheat (*Triticum aestivum* L. variety Fortuna) embryos (50 mg) were germinated in a Petri dish (60 × 15 cm) on four layers of 4.25-cm diameter Whatman No. 1 filter paper with 2 ml of water (containing chloramphenicol, 20 µg ml⁻¹) in the dark at 25 °C for 40 min or 5.5 h. The top layer containing the embryos was removed, blotted and placed in 0.5 ml of water containing chloramphenicol (20 µg ml⁻¹) and 50 µCi of purified 5-³H-uridine (25 Ci mmol⁻¹) for 15 min at 25 °C. The paper was blotted and the embryos were rinsed with water. Embryos were ground first with 0.5 ml of 10% TCA and then with 5 ml of 5% TCA. The homogenate was centrifuged for 10 min at 23,500g and the supernatant was kept. The pellet was rinsed three times by suspending in 5 ml of 5% TCA with a motor-driven Teflon homogeniser and centrifuging for 5 min at 23,500g. The pellet was then suspended in 1 ml of 0.1 N NaOH and counted in 10 ml of Triton X-100 toluene-based scintillation fluid. The TCA-soluble extract was prepared as before⁸. Unlabelled UTP (1 µmol) was added to the extract and concentrated down to dryness at 40 °C in a flash evaporator. A quarter of the sample was spotted on a PEI-cellulose TLC (Brinkmann) which was then developed in either 0.5 M KH₂PO₄, pH 4.5, or 0.4 M LiCl, pH 5.5. The UTP region on the PEI-cellulose was removed from the TLC sheet by treating with 1 ml of 2 M LiCl. The suspension was then mixed with 10 ml of liquid scintillation fluid (ACSTM, Amersham/Searle). The endogenous UTP was determined as before¹⁴. To prepare the RNA fraction, 50 mg of isolated wheat embryos was germinated as before and labelled for 30 min with 70 µCi of 5-³H-uridine. The embryos were ground first with 0.5 ml of high salt buffer (1 M KCl, 100 mM Tris-Cl, pH 7.6, and 5 mM EDTA). Sodium dodecyl sulphate buffer (3 ml of 1% SDS, 10 mM Tris-HCl, pH 7.6, and 5 mM EDTA) was added and the mixture was vortexed for 2 min. It was then extracted with water-saturated chloroform: phenol (1:1, v/v). The aqueous fractions were combined, mixed with two volumes of absolute ethyl alcohol and stored overnight at -20 °C. The precipitate was centrifuged at 23,500g for 20 min, rinsed three times with 5 ml of cold absolute ethyl alcohol, and then dissolved in 1 ml of 0.5% SDS buffer (0.5 M NaCl, 10 mM Tris-HCl, pH 7.6, 0.5% SDS and 1 mM EDTA). Sample of 40 µl was mixed with 10 ml of liquid scintillation fluid (ACSTM) and counted as before. The data represent an average of duplicate samples. Numbers in parentheses signify the fold increase of the 5.5-h values above those of the 40-min values.

Table 2 Cellular levels of nucleoside triphosphates in early germination of wheat embryos

Germination time	ATP	GTP pmol per mg of embryo	UTP	CTP
0	8	46	<1	<1
40 min	1,288 (1)	320 (1)	132 (1)	84 (1)
3 h	2,000 (1.6)	304 (1)	420 (3.2)	200 (2.4)
5.5 h	2,072 (1.6)	425 (1.3)	540 (4.1)	320 (3.8)

Adenine nucleotides were analysed by the method of Cheung and Marcus⁷. The key reaction is the phosphorylation of ADP by ³²P-PEP in a reaction catalysed by pyruvate kinase, with the extent of transfer of ³²P to ADP determined by adsorbing the nucleotides on to charcoal. ATP is determined as ADP after being converted quantitatively by hexokinase in the presence of excess glucose. Guanine ribonucleotides were determined according to Cheung and Marcus⁸. The principle of the assay is the conversion of GDP to ³²P-GTP utilising ³²P-PEP in the pyruvate kinase reaction. ³²P-ATP which is also formed as a major product is removed with glucose and hexokinase. CTP was determined with RNA polymerase^{13,14}. A reaction mixture in a volume of 100 µl, containing 12 mM MgCl₂, 80 mM KCl, 60 mM Tris-HCl, pH 7.6, Triton X-100 (0.02%), 0.9 U of *E. coli* RNA polymerase, 17.5 µg of calf thymus DNA, 50 nmol of GTP, 50 nmol of UTP, 2 nmol of ATP, 2.5 µCi of 8-³H-ATP (17 Ci/mmol⁻¹), and 50–200 pmol of CTP was incubated for 1 h at 37 °C. The suspension was then diluted with 5 ml of cold 5% TCA and filtered through glass fibre filters (Whatman GF/C). The filters were washed with 5 ml of 5% TCA, three times, dried and counted in 10 ml of toluene based scintillation solution. Figures in parentheses are as in Table 1.

the increase in RNA-synthesising capacity in the late germination phase.

Although the template activity of chromatin is essentially constant for the first 18 h of germination and active RNA polymerase is already present in the resting embryo, the amount of ribonucleoside triphosphates present in the resting embryo is almost negligible (Table 2). On the basis of these observations, we conclude that the rapid increase in the cellular content of purine and pyrimidine ribonucleoside triphosphates triggers the initial RNA synthesis once the wheat embryo is exposed to germination conditions.

We therefore propose that there are at least two stages of RNA synthesis in the early germination of wheat embryos. In the first stage (from 0 to 40 min), there is an increase in the four ribonucleoside triphosphates. In the second stage (from 40 min to 5.5 h), only the pyrimidine nucleoside triphosphate levels increase significantly. Thus the synthesis of RNA initially depends on the presence of all four ribonucleoside triphosphates. This is followed by a stage in which the pyrimidine ribonucleoside triphosphates determine the extent of RNA-synthesising capacity.

The mode of regulation of RNA synthesis in early germination of wheat embryo could be used as a working model for other biological systems. Changes in purine or pyrimidine pools may be used to explain the data of Hentschel and Tata¹⁵. They observed a differential activation of free and template-engaged RNA polymerase I and II during the resumption of development of dormant *Artemia gastrulae*. The level of uridine triphosphate has also been shown to control the growth in ascites hepatoma cells¹⁶.

We thank Dr Abraham Marcus for wheat embryos. This research was supported by a grant from the NSF.

Response properties of dipteran giant visual interneurons involved in control of optomotor behaviour

GIANT homolateral interneurons in the third optic ganglion of flies respond to visual stimulation with graded potentials only, lacking spike generation for signal transmission in physiological conditions¹. (The term 'homolateral' is used here in its anatomical connotation of neurones which are anatomically restricted to one side of the brain⁵.) Graded potentials were thought to be the means of signal transmission of all three classes of homolateral giant elements of this neuropile region, that is, the 'vertical cells' (V cells), the 'centrifugal horizontal cells' (CH cells) and the 'horizontal cells' (H cells): both CH and H cells are mainly sensitive to horizontal pattern movement, whereas the V cells respond mainly to vertically moving patterns^{1,2}. (The CH cells have an additional sensitivity to vertical, some V cells to horizontal pattern motion.) However, there is experimental proof that these findings might be valid only for the CH cells in which exclusively graded potentials could be recorded showing discrete excitatory and inhibitory postsynaptic potentials^{1,2}. For the V cells, however, it has been shown that spiking can be induced by application of hyperpolarising currents². In the absence of hyperpolarising currents, graded potentials with superimposed 'local' action potentials of small amplitude were observed^{1,2}. The H cells, on the other hand were reported to generate only 'local' action potentials superimposed on to postsynaptic slow potentials¹: these findings¹ are not compatible with the previous³ results or with the results presented here which demonstrate regular action potential activity in H cells in physiological conditions.

Intracellular recordings were obtained from various sites along the axons of horizontal cells. The site of penetration was not marked but could be estimated with high accuracy by using external landmarks of the neuropile for reference—for example tracheal patterns and borders of the ganglia. After obtaining the recordings, cells were marked by iontophoretic injection of the fluorescent dye Procion yellow M4RAN so that individual cells could be identified anatomically.

Figure 1 shows two of the three types of horizontal cells, one north cell (NH) and two equatorial cells (EH) following the terminology of Pierantoni⁴. Note that even the very fine dendritic processes are completely stained as comparisons with cells stained by other methods show^{5,6}.

Figure 2 shows intracellular recordings from the three cells shown in Fig. 1. In all three cases, the stimulus consisted of a moving pattern projected on to a circular milky glass screen. This moving pattern stimulated either the contralateral or the ipsilateral eye—the H cells have a binocular sensitivity—subtending a viewing angle of approximately 70° at the fly's eye. For all three recordings shown, the direction of pattern motion was such that the H cells reacted with excitatory responses. Figure 2a shows a d.c. recording obtained from the axon close to the dendritic tree in the lobula plate (see arrow), cell EH1. The cell's response was elicited by ipsilateral stimulation with a progressively moving pattern (that is, movement from the anterior to the posterior). A similar response can be obtained by recording from the dendritic branches in the lobula plate. It is clearly seen that strong excitatory and inhibitory postsynaptic potentials are superimposed, revealed by the steep depolarising

Fig. 1 Superimposed photomontages from serial frontal sections of Procion yellow-stained horizontal cells contrasting sharply against the autofluorescing background tissue. Second (medulla), third optic ganglion (lobula plate) and midbrain (protocerebrum) are shown in a view which is as seen when opening the back of the head capsule. NH, north horizontal cell; EH, equatorial horizontal cell; SH, south horizontal cell. Unstained cells show up very clearly as 'shadows' against the autofluorescing tissue, for example EH in the left lobula plate (close to the stained NH), and NH as well as SH in the right lobula plate (close to EH2). Arrows indicate approximate site of electrode penetration. The top of the figure corresponds to dorsal, the bottom part to ventral. aa, Axonal arborisation; at, axon terminals; cb, cell body; ch.int. chiasma interna; lob.pl., lobula plate; mb, mushroom body; med., medulla; oes., oesophagus; prot., protocerebrum.

and hyperpolarising potential flanks, respectively. In addition, a depolarising average membrane potential shift is observed. Figure 2b shows a recording from the axon of NH closer to the protocerebrum (in the optic peduncle connecting the lobula plate with the protocerebrum), that is, the recording was obtained close to the axonal arborisation (aa in Fig. 1) in the posterior slope. Presenting regressively moving patterns to the contralateral eye, very distinct excitatory postsynaptic potentials and rapid 'spike-like' potentials (the 'local action potentials' of Hausen¹) can be observed. For very effective stimuli, these spike-like potentials become superimposed. The ability of the axon to sum these spike-like potentials has been considered to be caused by a passively conducting membrane^{1,2}. In other words, the response shown in Fig. 2a and b can be obtained at any location along the axon. This is easily understood by calculating the space constant of such an axon which yields $\lambda = 1,000 \mu\text{m}$ (refs 1,2).

However, Fig. 2c shows a recording from a site proximal to the axonal arborisation (aa, Fig. 1). Again a regressively moving pattern was presented to the contralateral eye, using the same stimulating condition as for the experiments shown in Fig. 2b. It can be clearly seen that the cell is capable of generating regular regenerative action potentials; no slow membrane potentials accompany the action potentials. A refractory period was always detected—that is, we never observed 'superimposed spikes'. These results were not found to be cell specific, but representative for all H cells.

With high probability we can exclude the possibility that these findings (particularly the spiking activity of the axonal terminals of the H cells or the graduated potentials of the axon connecting lobula plate and protocerebrum) are injury potentials due to microelectrode penetration or to other unnatural conditions of the preparation. No changes in response properties were observed even after up to 80 min of intracellular recording time, and high frequency firing rates were not seen when cells were damaged by penetration. Furthermore, typical cell responses could be obtained from other cells even up to 2 h after obtaining recordings such as those shown in Fig. 2. However, definite proof would require the demonstration that the animal is capable of, for example, optomotor responses after penetration of such a cell.

These findings are consistent with the concept (to be fully discussed elsewhere (H.E.K., in preparation)) that (1) spikes are generated in the axon part between the axonal arborisation (aa) and the axonal terminals (at) and thus the 'local spikes' reflect the spike activity of the terminal axon part since these spikes are conducted retrogradely in the passive axon membrane distal to the axonal arborisation. (2) In addition to the ipsilateral input in the dendritic fan of the lobula plate, there is a second synaptic input region, which is most likely situated at the axonal arborisation and/or the axon terminals, and which is made by contralateral elements (see also ref. 1).

Thus the giant axon connecting the dendritic fan of the lobula plate with the input region in the protocerebrum could be used

Fig. 2 Intracellular recordings obtained from the H cells shown in Fig. 1 show responses to ipsilaterally presented progressive (a) and to contralaterally presented regressive pattern motion (b,c). Pattern parameters were: spatial wavelength, 20° ; contrast, $m = 48\%$; velocity, $w = 5 \text{ deg s}^{-1}$, luminance 4 cd m^{-2} . Arrows at the schematic horizontal cross section of the head (to the left of the response traces) indicate the direction of pattern movement.

for integrating ipsilateral as well as contralateral inputs. It is not clear whether the spike activity shown by these fibres represents the output of these cells or the contralateral input, but the former seems to be the more plausible interpretation³.

Directed outgrowth of optic fibres regenerating *in vitro*

THE way in which growing nerve fibres find their destined sites of termination is largely unknown, although there are supporting arguments and documentation for both local and long-range guidance mechanisms¹⁻³. Fibres regenerating following axotomy tend to grow in the direction of the degenerating tracts, apparently guided through channels formed by debris and/or glial cells^{4,5}. Here we present evidence that the neuritic outgrowth from goldfish retinal explants is related to the orientation of cut fibres within the explant.

We demonstrated previously that optic nerve crush 10-14 d before retinal explantation will stimulate neurite production in culture⁶ and that the neurites originate from ganglion cells⁷. On the day of explantation the retina is cut into square pieces $500 \mu\text{m}$ across, which are placed on a poly-L-lysine-coated substratum⁸. Several explants are placed in each 35-mm dish (NUNC) without regard to whether it is the vitreal or the photoreceptor surface that contacts the substratum. The ganglion cell axons in these experiments have been cut twice: once, at the time of optic nerve crush, several millimetres from the ganglion cell soma; and again, close to the soma when the retina is cut for explantation.

Examination of explant cultures under phase microscopy indicated that neuritic outgrowth began within a day of explantation. The direction of outgrowth was influenced by several factors. For example, neurites grown on poly-L-lysine-coated planar surfaces (glass or plastic) inevitably curved in a clockwise direction. Experiments designed to reveal the nature of this tendency led us to the conclusion that the directionality reflects an inherent helicity of the fibres⁹.

The clockwise directionality of neuritic growth is apparent in Fig. 1, which also indicates another property of the explants: the early outgrowth was usually restricted to one side or corner (Fig. 1a). A probable explanation for this asymmetric outgrowth was provided by explants stained with Holmes silver nitrate¹⁰. An array of parallel fibres could be seen in the optic fibre layer (Fig. 2), and the region of densest neuritic outgrowth was often aligned with this axis. Since the optic fibres in the goldfish retina, as in other vertebrates¹¹, are arranged in straight, radial lines, all of which converge at the optic disk where the fibres exit the eye as the optic nerve, it seemed probable that the parallel fibres within the explant were the ganglion cell axon tracts. Within the small area of the explant, convergence of the fibres was not apparent. Thus, it was not possible to determine which was the centripetal end of the fibre axis, so we could not establish whether the outgrowing fibres were indeed pointing at the phantom optic disk. In a brief, undocumented report 30 years ago, Vinnikov described directed outgrowth from retinal explants of several vertebrate species which he attributed to the radial pattern of optic fibres¹².

In order to establish definitively whether the neurites were aligned with the pre-existing ganglion cell fibre tracts within the explant, we performed the experiment represented schematically in Fig. 3. A strip of retina approximately $750 \mu\text{m}$ wide, extending across the full expanse of the retina from one peripheral margin to the other and including the optic disk, was prepared and then cut into thirds. Unlike our usual explants,

Fig. 1 Retinal explant viewed with darkfield illumination. The majority of neurites were restricted to one edge after 4 d *in vitro* (a). Note that most of them curve in a clockwise direction. After 14 d (b), neurites had grown out from the other edges as well. Scale bar, $500 \mu\text{m}$.

the orientation of each of these pieces was known. We expected no growth from the edges corresponding to the peripheral margins of the retina and very little from the two lengthwise edges, since the latter intersected few of the 'spokes' formed by ganglion cell axons. Further, we anticipated little growth from the central explant, since its ganglion cell axons would be aimed inward. The experimental results shown in Fig. 4 indicate that the neurites grew in the predicted direction. The pattern of outgrowth shown was observed in several replications and was independent of the placement of strips with respect to one another in the dish. The observed asymmetry of early outgrowth was thus a property of each piece of retinal tissue and did not reflect interaction between explants or other extrinsic factors.

Fig. 2 In this silver-stained explant (6 d *in vitro*), the optic fibre layer can be seen at the upper left; the edge of the explant lies between the two arrows. Neurites aligned or contiguous with fibres in the explant have grown out on to the substratum at the lower right. Scale bar, 25 μ m.

After several days in culture, the asymmetry of outgrowth was diminished as fibres emerged from the entire circumference of both the small, square explants (Fig. 1b; see also previous studies^{7,9}) and from the large strips. Examination of silver-stained explants offered a possible explanation for the eventual appearance of outgrowth from edges which were initially bare. Many of the later-appearing fibres had wandered through the explant or were deflected at the tissue-substratum boundary and grew along the edge of the explant for some distance before emerging on to the dish. In contrast, the first neurites seen probably regenerated from axonal stumps whose cut ends were lined up along the edge of the explant nearest the optic disk, so that their path was unimpeded as they grew out on to the substratum.

Fig. 3 The schematic diagram on the left shows the radial pattern of optic fibres in the retina. Ganglion cell somata are represented by small, open circles and their axons by line segments which converge at the optic disk (filled circle). At the upper right, the retina is shown as it was prepared for experimentation. A strip of retina that included the optic disk was divided longitudinally into three approximately equal pieces and then explanted. If the neurites maintained their centripetal orientation (towards the disk), they would grow out, as shown at the bottom right, from the ends labelled B and E.

Fig. 4 The results of an experiment as described in Fig. 3 are illustrated. After 6 d *in vitro*, most of the neurites have grown out as predicted from ends B (a) and E (c). The optic disk appears as a dark spot in b. Scale bar, 500 μ m.

The explants in Fig. 4 each contain approximately 5,000 ganglion cells¹³ from which axons regenerated in a direction predictable from their pre-existing pathways. While it is well known that growing axons can be guided both *in vivo* and *in vitro*^{1,14,15}, in these retinal explants a great many fibres have been channelled in the same direction in the absence of extrinsic influences. This preparation thus seems to provide a unique opportunity to directly examine retinal fibre-fibre interactions and their proposed role in neuronal recognition^{16,17}.

Neuromuscular transmission is adequate in identified abnormal dystrophic muscle fibres

It has been suggested that 'functional denervation', a failure of structurally intact neuromuscular junctions to evoke a muscle fibre action potential following nerve stimulation, plays an important part in the pathogenesis of murine muscular dystrophy^{1,2}. Other workers, however,

have been unable to confirm the existence of 'denervated' muscle fibres in dystrophic mouse muscle³. Moreover, the demonstration that transmitter release in response to nerve stimulation is normal in such muscle⁴ seems to preclude the possibility that 'denervation' may arise in an unpredictable or spasmodic way as a result of changes in transmitter store size or mobilisation during or after the repetitive discharge of the motoneurone. It has been considered possible, however, that the microelectrode techniques used in many of these studies do not always sample diseased muscle fibres, but select only a hypothetical group of 'normal' or 'healthy' muscle fibres. We have therefore applied a technique of intracellular staining^{5,6} and demonstrated that structurally abnormal muscle fibres in dystrophic muscle display normal neuromuscular transmission.

Experiments were carried out at room temperature on extensor digitorum longus (EDL) muscles removed from 3-6-months-old dystrophic (Bar Harbor 129 ReJ) mice and their clinically normal litter mates. In some muscles, muscle fibre action potentials were generated in response to indirect excitation and were recorded using standard intracellular techniques. In other muscles, endplate potentials (e.p.s) were recorded following nerve stimulation at frequencies of 3 Hz and 30 Hz in the presence of 0.6-1.2 μ M *d*-tubocurarine. The quantum contents of the e.p.s were estimated from the coefficient of variations of e.p.p. amplitudes⁷. After recording either action potentials or e.p.s, a second micro-electrode filled with a 4% (w/v) aqueous solution of Procion

Fig. 1 Two typical experiments in which the input resistance of a muscle fibre was recorded using a standard two microelectrode technique. The current passing electrode was filled with a 4% solution of Procion brilliant red. The hyperpolarisation of the membrane (lower trace) in the two fibres following the passage of current (upper trace) is shown in *a* and *b*. The muscle fibres were then marked with dye by passing steady d.c. current for 10-20 s. The marked fibres were located using fluorescence microscopy (*c*, *d*) stained for cholinesterase and teased from the whole muscle (*e*, *f*). The first fibre (*a*, *c*, *e*) showed longitudinal splitting, and dye injection had taken place at the site of splitting. The second fibre (*b*, *d*, *f*) was 'short' and had probably undergone necrosis. M.e.p.s were recorded from this fibre (not shown). Calibrations; *a*, *b*, 5 ms horizontal; 20 nA, 20 mV vertical; *e*, *f*, 70 μ m.

Fig. 2 An indirect action potential with its first derivative (*b*) was recorded from a dystrophic muscle fibre. The fibre was subsequently marked with Procion brilliant red and located using fluorescence microscopy (*c*). After staining for cholinesterase and teasing (*a*, *d*) the endplate cholinesterase (ep) and the site of the dye injection (PBR) were located. This fibre displayed longitudinal splitting, confirmed by serial section of the embedded fibre (*e*, *f*, *g*). Calibrations; *b*, 50 mV, 500 Vs⁻¹ vertical; 5 ms horizontal; *d*, 80 μ m.

Fig. 3 An indirect action potential with its first derivative (*c*) was recorded from a dystrophic muscle fibre which was marked with dye (PBR in *a*). This fibre was very short, and it terminated before the normal tendon of insertion (*a*). Its cholinesterase distribution appeared normal (*b*). Calibration; *c*, 50 mV, 500 V s⁻¹ vertical; 3 ms horizontal; *a*, 80 μm.

brilliant red H3BN (ICI, Blackley) was introduced into the muscle fibre within 100 μm of the recording electrode. Dye was ejected by passing inward direct current (20–80 nA; 10–20 s) through the dye-filled microelectrode. A visible red spot and a localised swelling of the muscle fibre indicated successful staining. Muscles were immediately fixed in cold (4 °C) formal-calcium (10% formalin, 1% CaCl₂) for 4 h, teased into small bundles and stained for cholinesterase activity⁸. The marked fibres were located using a Vickers Photoplan fluorescence microscope. The exciting light was filtered through a combination of Schott UG3, Schott BG12 and Balzers TRITC-I filters; emitted light was collected using a combination of Schott GG4 and Wratten 2E barrier filters. The marked fibres, which fluoresced bright red, were teased from the bundles, and, after photography, were embedded in 1% agar-agar, post-fixed in phosphate-buffered 4% glutaraldehyde (1 h) followed by phosphate-buffered 1% osmium tetroxide (15 min), and were then routinely processed and embedded in Spurr resin for subsequent microtomy. Sections were cut at 1 μm and were stained with hot toluidine blue.

The experiments indicated that grossly abnormal fibres in the dystrophic muscle were sampled using the described techniques, and two of these fibres are shown in Fig. 1. In 12 fibres indirect action potentials were generated and the fibres were subsequently marked with dye and teased out of the muscle. Ten of the fibres showed abnormalities such as

Table 1 Mean quantum content of e.p.ps evoked at 3 Hz and 30 Hz nerve stimulation in uninjected fibres and fibres injected with Procion brilliant red

	Mean quantum content	
	3 Hz	30 Hz
Normal EDL (unmarked)	306.3 ± 22.5 (14)	184.2 ± 15.8 (14)
Normal EDL (marked)	346.2 ± 51.9 (5)	232.0 ± 35.4 (5)
Dystrophic EDL (unmarked)	381.9 ± 47.1 (22)	233.4 ± 24.4 (22)
Dystrophic EDL (marked)	379.0 ± 127.4 (12)	243.9 ± 40.9 (12)

Fibres were injected from microelectrodes filled with a 4% solution of dye. Figures are mean ± s.e.m. Mean values at corresponding frequencies are not significantly different ($P > 0.05$; Welch test).

longitudinal splitting^{9,10} (Fig. 2) or necrosis (Fig. 3). In further 12 muscle fibres, the quantum content of the evoked e.p.ps was shown to be normal (Table 1); yet nine of the fibres show overt morphological abnormalities (Fig. 4 is typical).

We have thus demonstrated normal transmission in 20 dystrophic muscle fibres, 19 of which were grossly abnormal exhibiting between them longitudinal fibre splitting, necrosis and, apparently, termination within the bulk of the muscle rather than at the normal myotendinous junction¹¹. We suggest, therefore, that the pathological involvement of muscle fibres in this disease cannot be either a direct or indirect consequence of a peripheral block of neuromuscular transmission.

Fig. 4 Input resistance (*b*) and a train of endplate potentials (30 Hz, *c*) were recorded in the presence of *d*-tubocurarine from a dystrophic muscle fibre which was marked with dye (PBR in *a*). This fibre terminated well before the normal insertion of adjacent fibres. The cholinesterase staining was somewhat fragmented. The quantum content of the e.p.ps was normal (see Table 1). Calibration *a*, 50 μm; *b*, 60 nA, 60 mV vertical, 15 ms horizontal; *c*, 10 mV vertical, 1 s horizontal.

We acknowledge the support of the Muscular Dystrophy Group of Great Britain and the MRC. Richard Ribchester holds an MRC Studentship.

Neuromuscular blockade increases motoneurone survival during normal cell death in the chick embryo

NATURALLY occurring neuronal cell death is a quantitatively significant event in many developing systems¹⁻⁵; however, the determinants responsible for some neurones surviving while an equal or even greater number degenerate are still unknown. Neurones which undergo spontaneous degeneration have axons in the appropriate peripheral area^{6,7}, and it is generally believed that those neurones which die do so because they are losers in a competition for a limited number of 'targets'^{11,8}, or a limited amount of 'trophic substance'^{9,10}. This study was undertaken in an attempt to better understand the parameters which define a 'target' and the factors involved in the survival and degeneration of motoneurones in the lateral motor column of the lumbar spinal cord of the chick. Normally by embryonic day 6 a peak of approximately 22,000-24,000 motoneurones is found in each lateral motor column whereas by day 9 there are 13,500 and by day 12, and continuing through hatching, each lateral motor column consists of 11,000-11,500 motoneurones (unpublished data, also see refs 3, 11). We report here that contrary to what might be expected¹², embryos treated during the period of normal cell death with botulinum toxin (BTX) or curare contain about 5,500 more motoneurones (a 50% increase) in each lateral motor column after the period of cell death is over. Treatment with the irreversible nicotinic receptor blocker α -cobratoxin (CT, from *Naja naja siamensis*) also produced an increase in motoneurone survival; however, no studies were carried out with this agent beyond day 10.

Drugs were administered either by intramuscular (i.m.) injection (0.05-0.25 μ l) into the right leg (ventral muscle mass) on day 6 using a 33 gauge Hamilton microsyringe fitted with a 40- μ m glass tip¹³ (CT, BTX, and sterilised BTX), or by dropping the solutions (0.1-0.25 ml) on to the vascularised chorioallantoic membrane (curare and CT) on days 6, 7, 8, and 9. Embryos were killed for cell counts either on day 10 or day 16. After treatment with pre- or postsynaptic blocking agents a single leg at day 16 was capable of maintaining 50% more motoneurones (Fig. 1, Table 1). This increase did not seem to be a transient effect, as there were comparable numbers of neurones present in treated embryos on days 10 and 16. Moreover, no increase in neurone survival was found in embryos that were injected with curare after the period of cell death was over (group curare II in Table 1). Also, there was no enhancement of neuronal survival when drug treatment was not effective for the entire period between days 6 and 10 (group CT II).

Fig. 1 Cross section through the spinal cord (fourth lumbar segment) of 16-d control (a, 20 \times ; b, 51 \times) and curare-treated (curare I; c, 20 \times ; d, 51 \times) embryos. The lateral motoneurones are the cluster of large dark staining cells in the ventro-lateral part of the cord. Spinal cords from BTX-treated embryos appear very similar to those from curarised embryos.

Curare, CT and BTX all decrease the amount of acetylcholine interacting with receptors, thereby reducing muscle contraction and motility. Motility levels are, therefore, a rough index of the drug's ability to interfere with normal neuromuscular function. All treatments which increased motoneurone survival produced either a partial or total inhibition of neuromuscular activity from day 6-10, and continued to decrease motility at least until day 16 (Table 1). Embryos in group CT II received a single injection of cobratoxin on day 6 which totally stopped all overt motility for the first half of the cell death period (day 6-7 $\frac{1}{2}$), whereas after day 8 motility levels were similar to controls. Interestingly, these embryos showed no increase in motoneurone numbers after killing on day 10. This suggests that either the critical period for increased cell survival occurs after day 8 or that once activity returns to near normal levels on day 8-8 $\frac{1}{2}$, 'redundant' synapses are lost, leading to a degeneration of the excess neurones.

The additional motoneurones present on day 16 seem to be uniformly distributed throughout the lateral motor column except for the most rostral segments (Fig. 2)—this distribution is very similar to the spatial distribution of 'hypothanasia' seen after transplanting additional limbs on to the body wall¹⁴. This may imply that virtually all muscles in the leg are capable of maintaining additional motoneurones. Other interpretations

Fig. 2 Motoneurone counts in the right lateral motor column in lumbar segments 1-9 of 16-d control (▲) and curare-treated (●, curare I) embryos. Counts for every tenth section are represented. Note the increased cell number in segments 3-9 for curare-treated embryos. Motoneurone distribution after BTX treatment is basically the same as that after curare.

Table 1 Number of motoneurons and levels of embryonic activity after treatment with curare, botulinum toxin (BTX) and α -cobratoxin (CT)

Data are expressed as the mean \pm s.d. Abbreviations: LMC, lateral motor column; CAM, chorioallantoic membrane; LD₅₀, 50% lethal dose for a 20g mouse. Weights of shank muscles (g) at day 16 were: control, 0.38 \pm 0.04; BTX, 0.27 \pm 0.02; curare, 0.26 \pm 0.05. Lumbar cords were run up for paraffin histology, serially sectioned at 12 μ m, stained in thionine and the motoneurons in either one or both LMCs were counted in every tenth section^{9,11}. For groups in which counts of only one LMC are presented, at least one animal in each group was counted on both sides to assure that no discrepancies existed between right and left LMCs following treatment. The injection procedure itself did not produce any noticeable motoneurone degeneration (see groups CT II, and sterilised BTX); however, as an added precaution, only the left LMC was counted in BTX embryos. Motility recordings for CT I and curare-treated embryos between day 6 and 10 were made just before the daily drug treatment (that is, 24 h after the last treatment). Previous observations¹⁹ have shown that 2.5 mg of curare stops all activity for much of the 24-h period, followed by a subsequent slow rise in motility. Therefore, the activity levels presented represent the maximum activity for the preceding 24-h period.

*Number in group given in parentheses.

†Sample size for motility recordings on days 7–15 was $n = 5$; for day 16, $n = 8$.

‡Embryos were also recorded between days 10 and 16 but for illustrative clarity the data are not shown here. The average rate of motility during this time was about 8 per min compared to 16–22 per min for controls.

are possible, however, such as a preferential alteration of either fast or slow muscle properties and/or an increased number of axons forming synapses outside their normal area of innervation.

Our data show that decreasing functional activity at the neuromuscular synapse is correlated with an increase in the survival of motoneurons normally destined to undergo natural cell death. As has been previously reported^{15,16} curare, BTX and CT produced muscular atrophy; therefore, the possibility that an increase in the size or number of muscle fibres is responsible for the maintenance of the additional neurones is unlikely. It seems most likely that muscle fibres, which in normal conditions would maintain only one neurone, are capable of accepting and maintaining additional neurones after treatment. One explanation for this may be that normally the first axon to contact the myotube alters the membrane-receptor characteristics such that those parts of the myotube membrane not adjacent to the nerve terminal are rendered refractory to other axons. By blocking this initial nerve-muscle interaction we may have altered this process so that the myotube becomes receptive to additional axons^{17–19}. Alternatively, it might be that once the axon contacts the myotube and initiates contractions, there is a period in normal development during which the muscle membrane properties (ACh receptor number or distribution?) are changing as a result of the increased activity. Before and during this critical period, more than one neurone could be maintained by each myotube; however, once the number of contractions reached a critical level, the membrane properties would be altered such that only one neurone could be 'supported', and additional contacts would be lost. By decreasing myotube contractions with curare, BTX or CT, the critical period would be maintained with a resulting increase in motoneurone survival. The normal number of motoneurons present on day 10 in embryos which had a motility deficit before but not after day 8 (group CT II) could be accounted for by either model. Preliminary studies

with embryos in which motility is depressed from day 6–10 by daily injections of cobratoxin indicate that once motility returns to control levels (day 12–13) the additional neurones that are present on day 10 are lost; a finding which is also consistent with both models. The critical difference between the two models is that in the latter, but not the former, contact of the myotube by more than one axon is postulated to be a normal, though transient, process. We are carrying out experiments that may distinguish between these two alternatives.

Although our results support the idea that it is a limiting of 'targets' rather than of 'trophic substance' that is the important factor in naturally occurring cell death, in the future it may be neither profitable nor possible to draw any useful distinction between these two. We therefore emphasise that the novelty of our results is that they strongly implicate physiological activity at the neuromuscular synapse in the control of cell survival. Our results also support the suggestion that neurones which undergo normal cell death may form connections before spontaneous degeneration^{1,3}.

Gating properties of acetylcholine receptor in newly formed neuromuscular synapses

A FOREIGN motor nerve transplanted on to an adult innervated muscle will not form functional neuromuscular synapses¹, yet several experimental procedures, such as denervation or muscle crush, change the properties of the muscle membrane so that a foreign nerve can establish 'ectopic' synapses in a normally endplate-free region of the muscle²⁻⁴. The nerve thereby induces a localised area of high acetylcholine receptor (AChR) density in the extrajunctional membrane⁵. Denervated or previously crushed muscle fibres already have, before synapse formation, low density AChRs in the extrajunctional membrane^{6,7}. The extrajunctional AChRs are different in a number of respects from those in the junctional membrane⁸⁻¹¹. The question is, therefore, whether the AChRs of an ectopic synapse have properties similar to junctional or to extrajunctional AChRs.

The two types of AChR differ in their gating properties, since the mean open time of extrajunctional channels is about 3 to 5 times that of junctional channels¹²⁻¹⁴. We have therefore measured the mean open time and the mean conductance of ion channels of ectopic synapses in frog (*R. temporaria*) sartorius muscle by analysing acetylcholine (ACh)-induced membrane current noise^{11,15}. The results indicate that the gating properties of ion channels in ectopic synapses are similar to those of normal synapses.

The tibialis nerve was connected to the tibial endplate-free zone of sartorius muscle. At the same time the muscle was cut or crushed near the site of implantation^{3,4}. In the majority of experiments 2 to 3 months later a connective septum has formed at the site of muscle crush, isolating muscle fibres of about 3-5-mm length extending between the septum and the tibial myotendinous junction. Most of these fibres respond to electrical stimulation of the tibialis nerve with an action potential or subthreshold endplate potentials (e.p.ps), and in some fibres low frequency (< 1 min⁻¹) miniature endplate potentials (m.e.p.ps) can be recorded^{3,4}. Occasionally, doubly innervated fibres are encountered which can be stimulated both by the tibialis and the sartorius nerve.

Examination of ACh sensitivity of tibialis-innervated fibres by focal iontophoretic application of ACh along a fibre reveals a peak of sensitivity at the site of the ectopic synapse. When these muscles are exposed to ¹²⁵I- α -bungarotoxin (BuTX), in most fibres several patches of high grain density are seen in the autoradiogram. The shape of these patches is round or elongated and they range in size from 5 to 30 μ m. In some fibres where elongated patches are present, few or no grains at all are seen on the rest of the fibre (Fig. 1a). In other fibres the rest of the membrane is also strongly labelled. Similar patches of high grain density are also found in muscles in which the tibial nerve had failed to establish synapses, for example, as a result of nerve displacement after the operation (Fig. 1b). They probably correspond to 'hot spots'^{16,17} found also in chronically denervated frog cutaneous pectoris muscle (A. Michler, personal communication). At present, we have no clue as to which of the patches found in innervated muscles corresponds to an ectopic endplate and which to a 'hot spot'.

Fig. 1 Autoradiograms of muscle fibres isolated from the tibial portion of operated sartorius muscle. At the time of initial operation, the muscle was cut 5-10 mm away from its tibial insertion and the tibialis nerve was implanted into the remaining tibial portion. Several months later, muscles were exposed for 2 h to 1 μ g ml⁻¹ ¹²⁵I- α BuTX (specific activity: 4.7×10^5 Ci mol⁻¹) and subsequently fixed in glutaraldehyde. Single fibres were teased and dipped in Ilford L4 emulsion and exposed for 24 h. *a*, Elongated patch of high grain density in a fibre from a muscle which responded to stimulation of the tibialis nerve. Experiment 116 d after operation. *b*, Patches of high grain density ('hot spots') in a fibre from a muscle in which the tibialis nerve did not make contact as a result of mechanical displacement. The fibres were in effect chronically denervated for 89 d. Scale bar, 20 μ m.

A tentative hypothesis is that the elongated patches in fibres with otherwise low grain density (Fig. 1a) represent ectopic endplates.

To study their channel properties, superficial ectopic endplates were voltage clamped to a holding potential between -70 mV and -90 mV. Membrane currents of 15 to 130 nA mean amplitude were induced by releasing ACh from a micropipette located 30-50 μ m above the synapse. During ACh application, the clamp current fluctuates around its mean in a manner similar to that described for normal endplates. The autocorrelation function of ACh-induced current noise¹² shows a single decay constant τ_{noise} , the value of which varied between 1.36 ms and 1.85 ms in seven experiments carried out at 15-18 $^{\circ}$ C, the mean value being $\tau_{noise} = 1.5 \pm 0.3$ ms (\pm s.e.m.). The values of individual experiments were normalised to -80 mV membrane potential and 18 $^{\circ}$ C assuming¹⁵ a Q_{10} of 2.77 and an e -fold increase of τ per 80 mV hyperpolarisation. The mean value of τ_{noise} which is an estimate of the channel open time^{11,15} is thus very similar to that reported for normal synapses in *R. temporaria*¹². The result of one experiment is shown in Fig. 2a.

The size of the single channel current i obtained from the ratio of the variance σ^2 of the current fluctuations to the mean current I was more variable and ranged between 0.7 pA and 1.7 pA in these experiments. The reversal potential of nerve-evoked endplate currents (e.p.cs) in ectopic synapses was determined in three experiments and was found to be between -5 mV and 0 mV (Fig. 3). This is very similar to what has been reported as a reversal potential for e.p.cs evoked by nerve stimulation or iontophoretic ACh application at normal synapses^{18,19}. The size of the elementary conductance change has a mean value of $\gamma = 16 \pm 1.4$ pS (range 10-21 pS, seven experiments, reversal potential assumed at 0 mV) and is thus somewhat lower than the value obtained previously for normal synapses¹².

A possible reason for the lower estimate of γ in ectopic synapses as compared to normal synapses could have been that during ACh application an appreciable fraction of all available receptors is liganded, since AChE activity is low in these synapses. Therefore, the low concentration limit required for estimating i from the ratio σ^2/I might not hold and i would be underestimated²⁰. This was tested in one experiment by inducing mean membrane currents which varied in size over a fourfold range. In this experiment, the estimate of γ was independent of the magnitude of the mean current. Another possibility for the smaller estimate of γ might be that in most experiments a relatively high concentration of Mg^{2+} was present in the bathing solution.

Fig. 2 Analysis of endplate currents at ectopic synapse. All experiments were carried out in frog Ringer solution of the following composition (in mM): NaCl, 114; KCl, 2.5; CaCl₂, 0.5–1; MgCl₂, 0–15; Na₂HPO₄, 2.15; NaH₂PO₄, 0.5; pH, 7.1. MgCl₂ was added in five out of seven experiments to abolish nerve-evoked muscle contraction. Superficial ectopic synapses were located by the rise time of e.p.ps 97 and by applying hypertonic sucrose from a blunt micropipette along the fibre. A brisk increase in m.e.p.p. frequency indicated the site of innervation. *a*, The graph shows the autocorrelation function of ACh-induced voltage clamp current fluctuations. Data points represent value of autocorrelation function $\Phi(T)$ for different time intervals T . Time course of endplate current during iontophoretic ACh application is shown in the inset (calibration marks indicate 20 nA and 25 s). A current sample of 6.4 s duration, taken during the peak of the response, was used for calculation of autocorrelation function. Mean amplitude: $I = 43$ nA. The record was filtered with a band pass (0.5 Hz–2.5 kHz). Sampling interval 100 μ s. Control data obtained from a current sample in the absence of ACh was subtracted. Continuous line is an exponential function fitted by eye to the data points. It yields a value of $\tau = 1.6$ ms for the time constant and an extrapolated ordinal intercept of $\sigma^2 = 6.1 \times 10^{-20} A^2$ for the variance of ACh-induced current fluctuations. Holding potential: -80 mV. Temperature $18^\circ C$. Experiment performed 104 d after implantation of the tibialis nerve. *b*, Upper two traces: Examples of m.e.p.cs recorded from the same fibre as in (*a*), $\tau_{m.e.p.c.} = 3.4$ ms. Bottom trace: m.e.p.c. from another fibre with extremely long decay time $\tau_{m.e.p.c.} = 12$ ms at -80 mV membrane potential and $18^\circ C$. Time constant of current fluctuations in this fibre was $\tau_{noise} = 1.8$ ms.

Whereas the elementary conductance events in normal and ectopic synapses are similar, the time course of miniature endplate currents (m.e.p.cs) is different in the two types of synapses. In a normal synapse the m.e.p.c. decay time constant $\tau_{m.e.p.c.}$ is similar or identical to the mean open time of ion channels as derived from noise analysis¹⁵. In all ectopic synapses studied, $\tau_{m.e.p.c.}$ was longer by a factor of 2 to 6 than τ_{noise} and ranged from 3.3 ms to 12.6 ms (see Fig. 2*b*, Table 1). In contrast to the relative uniformity of τ_{noise} in different fibres, the value of $\tau_{m.e.p.c.}$ changed from fibre to fibre. This is similar to what is observed at normal endplates after inhibition of AChE, suggesting that the AChE activity in ectopic synapses is low compared to that in a normal synapse. In most ectopic synapses we failed to detect AChE activity histochemically by the Karnovsky method²¹, even after several hours of incubation and despite intense staining of myotendinous junctions which were only a few millimetres away. We also found in three experiments that adding 3–6 μ M neostigmine

Fig. 3 Determination of reversal potential of nerve-evoked e.p.c. in a newly formed synapse. Membrane potential was clamped to the value indicated beside each trace and 20–50 responses were averaged at each potential level. Arrow indicates time of tibialis nerve stimulation. E.p.c. reverses sign between -5 mV and 0 mV membrane potential. Experiment was carried out 89 d after operation.

Table 1 Comparison of mean channel open time and mean m.e.p.c. decay time constants obtained from the same ectopic synapse					
Experiment	τ_{noise} (ms)	$\tau_{m.e.p.c.} \pm s.e.m.$ (ms)	Membrane potential (mV)	Temperature ($^\circ C$)	Time after operation (d)
1	1.58	3.76 (0.09)	-80	17	90
2	1.82	5.14 (0.21)	-70	15	91
3	1.85	12.23 (0.35)	-80	18	93
*4	1.61	3.36 (0.29)	-80	18	115
*5	1.52	6.96 (0.35)	-80	18	113
6	1.71	—	-70	16	81
7	1.45	4.22 (0.15)	-90	16	97

$\tau_{m.e.p.c.}$ represents mean values obtained from 9 to 25 individual m.e.p.cs. Time after operation refers to the time between implantation of the tibialis nerve and the time the experiment was carried out.
*Experiments done in frog Ringer solution with no Mg^{2+} ions present. In the remainder Mg^{2+} concentration varied between 5 and 15 mM.

to the bath prolonged $\tau_{m, e.p.c.}$ by a factor of less than 1.25 as compared to a factor of 2 reported for normal neuromuscular synapses^{22,23}.

We have shown that ion channels associated with AChRs of newly formed ectopic synapses on adult muscle are similar in their gating properties to those found in normal endplates. They are different from those of extrajunctional AChRs found in denervated fibres not contacted by a nerve. The question arises as to whether, during synapse formation in adult fibres, extrajunctional AChRs are accumulated under the influence of the motor nerve, as has been shown recently for embryonic amphibian muscle²⁴ and are changed in their properties to junctional AChRs, or whether the motor nerve induces synthesis of 'junctional' receptors at its site of contact. Experiments carried out at early stages of synapse formation may help to answer this question.

We thank Professor J. Schmidt for ¹²⁵I- α -BuTX and Ms A. Michler for help with autoradiography. H. R. Brenner was supported by the Schweizerische Nationalfonds.

Direct or proximate contact between cells and metabolic activation systems is required for mutagenesis

THE adverse biological effects of most carcinogens and/or mutagens are dependent on the formation of electrophilic intermediates which react with nucleophilic groups in cellular macromolecules. Inclusion of a metabolic activation system in various assays enables the detection of mutagenic activity for carcinogens and/or mutagens which require such metabolic activation. In mutagenesis assays, using mammalian cells, two metabolic activation systems have been used: cell-mediated mutagenesis (CMM), in which cells are co-cultured with metabolically competent, but lethally irradiated, cells (feeder layer)^{1,2}, and microsome-mediated mutagenesis (MMM), in which cells are treated with chemicals in the presence of a microsomal fraction from rodent livers and an NADPH-generating system^{3–5}. The present study was carried out in order to investigate whether direct or proximate contact between target cells and such mediators of metabolism is necessary for the induction of mutagenesis. The results suggest that such contact is essential in both cell- and microsome-mediated mutagenesis of mammalian cells and, possibly, also in bacterial systems.

Fig. 1 Schematic representation of the experiments using CMM or MMM systems, which were designed either to allow or to prevent contact between the V79 cells and metabolic activation systems. Experimental procedures for CMM were adopted from Huberman and Sachs¹. Following irradiation at 4,000 R, secondary cultures of BDV1 rat embryo cells were plated at 2.5×10^6 cells per 60-mm dish (feeder layer) and, 5 h later, 3.0×10^6 V79 cells were plated and cultured overnight in Eagle minimum essential medium plus 10% foetal calf serum (FCS). The next day, cultures were treated with 7,8-diol BP (obtained from Dr P. L. Grover, Chester Beatty Research Institute), dissolved in DMSO, at concentrations of 1 and 2 nmol ml⁻¹ (8 ml per dish) for 48 h, followed by plating for determination of induced cytotoxicity and mutagenicity. Experimental procedures for MMM have been described elsewhere⁵; in brief, the V79 cells (overnight culture after plating 1.5×10^6 cells per 60-mm dish) were incubated for 2 h in 2.5 ml of the reaction mixture, either in liquid suspension or suspended in 0.5% agar. The reaction mixture consisted of 0.75 ml post-mitochondrial fraction from phenobarbitone-pretreated BDV1 rat livers (1 mg ml⁻¹ in drinking water for 7 d), 0.75 ml modified Sørensen phosphate buffer (0.055 M, pH 7.4, containing 0.9% NaCl and 1.6 mg ml⁻¹ MgCl₂·6H₂O) and 1.0 ml PBS containing 12.5 μ mol glucose-6-phosphate and 2 μ mol NADP⁺. The cells were then washed twice and incubated for 2–3 h in fresh culture medium, followed by plating for determination of induced cytotoxicity and mutagenicity. Cytotoxicity was determined by plating 100 cells per 60-mm dish (four dishes at each point) and culturing for 7 d. For mutagenesis, 2×10^4 and 10^5 cells per 60-mm dish were plated for *aza* and *oua* respectively (eight dishes at each point). After an expression period of 2 d, selection drugs were added to give final concentrations of 20 μ g ml⁻¹ 8-azaguanine or 1 mM ouabain. The media containing drugs were changed once, 5–7 d later; for the 8-azaguanine medium, FCS was replaced by dialysed FCS and non-essential amino acids were added at 0.1 mM. The cultures were fixed and stained with Giemsa 12 d (*aza*) or 14 d (*oua*) after plating. Mutation frequency was calculated per 10^5 survivors, taking into account the number of cells plated and the plating efficiency. The stability of *aza* and *oua* was demonstrated using 10 and 11 isolated colonies, respectively, which were cultured for more than one month in the absence of the drug used for selection⁶. *a*, Conventional CMM and MMM systems, as described above, in which the V79 cells are allowed to remain directly in contact with the cells or microsomes carrying metabolic activating enzymes. *b*, Is designed to separate the V79 cells from the metabolic activation system. In the CMM system, a glass cover slip (24 \times 40 mm) on which 1.4×10^5 V79 cells were plated and cultured overnight, was supported above the feeder layer at a distance of approximately 1 mm. In the MMM system, 2 ml of 0.5% agar in PBS was poured on the V79 monolayer (approximately 1 mm in thickness) and, after hardening, the reaction mixture suspended in 0.5% agar was added. *c*, In the CMM system, the V79 monolayer was grown on a cover slip and placed directly on the feeder layer. In the MMM system, the reaction mixture was suspended in 0.5% agar and poured directly on the V79 monolayer.

Mutations in two genetic loci, comprising 8-azaguanine resistance (*aza*) and ouabain resistance (*oua*), were studied using V79 Chinese hamster cells. Mutations were induced either by *trans*-7,8-dihydroxy-7,8-dihydrobenzo[*a*]pyrene (7,8-diol BP) at concentrations of 1 and 2 nmol ml⁻¹ in the CMM system, or by *N*-nitrosodimethylamine (DMN) at concentrations of 10 and 30 μ mol ml⁻¹ in the MMM system. Both these chemicals require metabolic activation^{3,5}. As shown in Fig. 1, the following experiments were designed either to allow, or to prevent, contact between the V79 cells and the feeder layer, or the microsomes carrying the enzymes responsible for metabolic activation: *a*, conventional mutagenesis assays

were used. In the CMM system the V79 cells were grown directly on the feeder layer of rat embryo cells and, in the MMM system, the cells were incubated in the presence of a reaction mixture containing a post-mitochondrial liver fraction from phenobarbitone-pretreated rats and co-factors; *b*, to separate the V79 cells from the feeder layer in the CMM system, a glass cover slip, on which a monolayer of the V79 cells had been grown, was placed above the feeder layer at a distance of approximately 1 mm. In order to maintain a constant distance between the two cell layers, the cover slip was supported by two strips of silicone rubber and pressed down with two metal cylinders used for colony isolation. In the MMM system, the V79 cells were separated by an agar layer (0.5% in phosphate-buffered saline, PBS) at a distance of approximately 1 mm from the reaction mixture, suspended in agar; *c*, this was designed as a control of the experimental conditions described in *b*. In the CMM system, the V79 monolayer, on a cover slip, was placed face down, directly on the feeder layer and was pressed down with two metal cylinders to ensure maximum contact between the two cell layers. In the MMM system, the reaction mixture suspended in agar was poured directly on to the V79 monolayer.

Figure 2 shows the mutagenicity of 7,8-diol BP in CMM; it produced *aza* and *oua* in a dose-related fashion when the V79 cells were cultured on the feeder layer in the conventional CMM assay (*a* in Fig. 1). No mutations were induced, however, either when the V79 cells were separated at a distance of approximately 1 mm from the feeder layer (*b* in Fig. 2), or when the V79 monolayer grown on the glass cover slip was placed directly on to the feeder layer (*c* in Fig. 1). In the latter, growth of the V79 cells was considerably reduced, presumably due to lack of circulation of nutrients under the cover slip; doubling time was more than 60 h compared with 15–16 h for the other systems (*a* and *b*). The results indicate that 7,8-diol BP, one of the metabolites of BP, is further metabolised in the CMM assay to an ultimate form, possibly 7,8-dihydroxy-9,10-epoxy-7,8,9,10-tetrahydrobenzo[*a*]pyrene (7,8-diol-9,10-oxide BP)⁶⁻⁸, which could be transferred to the target cells through direct or proximate contact with the feeder layer.

Similar results were obtained in the MMM assay (Fig. 3). Treatment of the cells with DMN in the presence of post-mitochondrial liver fraction and cofactors, either in liquid (*a* in Fig. 1), or in agar (*c* in Fig. 1), induced dose-related cytotoxicity and mutagenicity. However, neither cytotoxicity nor mutagenicity were induced when the cells were separated by the agar layer approximately 1 mm thick (*b* in Fig. 1). This lack of induction could be explained either by the requirement of direct contact or close proximity between the target V79 cells and microsomes carrying metabolising enzymes, or by the decomposition or trapping of methylating intermediates formed from DMN in the separating agar layer. The former possibility is further suggested by a conventional MMM assay in which the V79 monolayer was treated with DMN at 30 $\mu\text{mol ml}^{-1}$ in different volumes of the reaction mixture in

Fig. 2 Cytotoxicity (A) and mutagenicity (B, *aza*; C, *oua*) induced by 7,8-diol BP at concentrations of 1 and 2 nmol ml^{-1} in the CMM assay. ●, The conventional CMM assay (*a* in Fig. 1) in which the V79 cell grew directly on the feeder layer. ○, *b* in Fig. 1, in which the V79 cells were separated from the feeder layer. □, *c* in Fig. 1, in which the V79 monolayer was placed on the feeder layer. Cytotoxicity was expressed as percentages of plating efficiency of the solvent (DMSO) control. Mutation frequencies were expressed as the number of drug resistant clones per 10^5 survivors. *oua* in Fig. 1c at 2 nmol ml^{-1} was not examined. Bars indicate s.e.; when not indicated, s.e. are within the circles.

liquid (0.5, 1.5 and conventional 2.5 ml, which correspond approximately to 0.25, 0.75 and 1.25 mm in depth, respectively). The mutation frequencies obtained (mean number of resistant clones per 10^5 survivors, \pm s.e.m.) were 173 ± 18 , 212 ± 26 and 171 ± 19 for *aza* and 41 ± 4 , 60 ± 5 and 50 ± 4 for *oua*, respectively indicating that induction of mutations may take place independently of the total volume, in the thin layer of the reaction mixture.

In the experiment shown in Table 1, V79 cells were treated with a directly acting mutagen, *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG), while separated from the MNNG-containing agar medium by an agar layer of varying thickness (approximately 0.5, 1.0 and 1.5 mm). No decreases in the induction of cytotoxicity and mutagenicity were observed when the cells were separated from the MNNG medium. There was also no difference in MNNG-induced mutation frequency between liquid and agar medium. These results indicate that agar did not trap or interfere with the diffusion of MNNG,

Table 1 MNNG-induced cytotoxicity and mutagenicity when the cells were separated from MNNG-containing agar medium by agar layers of varying thickness

Treatment		Agar layer for the separation		P.E. (%)	Mutation frequency	
		volume (ml)	thickness (mm)		<i>aza</i>	<i>oua</i>
DMSO	liquid	0	0	93.5 ± 4.8	4.0 ± 1.9	0
MNNG	liquid	0	0	66.0 ± 2.9	46.6 ± 3.6	4.7 ± 1.0
MNNG	agar	0	0	68.3 ± 7.7	46.6 ± 5.8	4.6 ± 1.2
MNNG	agar	1	0.5	58.3 ± 4.4	47.3 ± 6.5	5.2 ± 1.3
MNNG	agar	2	1.0	65.8 ± 4.0	50.4 ± 5.4	4.8 ± 1.4
MNNG	agar	3	1.5	51.8 ± 2.0	66.7 ± 9.1	11.1 ± 1.6

V79 cells were plated at 1.5×10^6 cells per 60-mm dish, cultured overnight and then treated with MNNG at 4 nmol ml^{-1} (4 ml per dish), either in liquid medium, or in 0.5% agar medium, for 2 h. The cells were separated from the MNNG-containing medium by agar layers (0.5% in phosphate-buffered saline (PBS), approximately 0.5, 1.0 and 1.5 mm in thickness, corresponding to 1.0, 2.0 and 3.0 ml of agar suspension. The cultures were then washed three times and cultured in a fresh culture medium for 2–3 h, followed by plating for determination of induced cytotoxicity and mutagenicity (see the legend for Fig. 1). This replating procedure produced a lower mutation frequency, approximately 20% for *aza* and 8% for *oua*, as compared to the conventional *in situ* treatment.

Fig. 3 Cytotoxicity (A) and mutagenicity (B, aza; C, oua) induced by DMN at concentrations of 10 and 30 $\mu\text{mol ml}^{-1}$ in the MMM assay. ●, The conventional MMM assay (a in Fig. 1) in which the V79 monolayer was incubated in the presence of the reaction mixture in liquid suspension. ○, b In Fig. 1, in which the V79 cells were separated by an agar layer from the reaction mixture suspended in agar. □, c In Fig. 1, in which the reaction mixture suspended in agar was poured directly on to the V79 monolayer. Cytotoxicity and mutagenicity are expressed as described in the legend to Fig. 2.

an alkylating agent that is relatively stable (half life is 90 min^{10,11}).

These results suggest that direct or proximate contact between the target cells and membranes of the cells or microsomal particles, carrying carcinogen-metabolising enzymes is essential in cell- and microsome-mediated mutagenesis of mammalian cells. This requirement may also hold true for mutagenesis assays using bacteria and microsomes. Glatt and Oesch¹², using electron microscopy, have demonstrated tight binding of microsomal particles to *Salmonella typhimurium* TA98, suggesting the importance of such a direct contact in bacterial systems.

Two mechanisms are plausible in explaining why direct or proximate contact is required. One is the chemical instability of the ultimate reactive metabolites formed, which, in many cases, are short-lived intermediates. For example, the half lives of synthetic 7,8-diol-9,10-oxide BP, an ultimate form of 7,8-diol BP, is 0.5 min for the *syn* isomer and 2.5 min for the *anti* isomer in aqueous media⁹; the half life of methylating intermediate(s) formed from DMN by liver microsomal monooxygenases was measured to be of the order of seconds (A. Barbin & H. Bartsch, personal communication). Such unstable compounds may thus decompose in aqueous media before reaching the DNA of the target cells, unless the distance of migration is reduced to a minimum. Second, when ultimate metabolites with lipophilic properties are formed, they could reach the target cells by transfer through the lipid matrix of membranes. This would require direct contact between the target cells and the metabolic activation systems. Such lipophilic environments may eventually contribute to a prolonged half-life of reactive compounds and may prevent contact with inactivating enzymes, such as glutathione S-transferases present in the cytosol¹².

Ascorbate-enhanced cytotoxicity of misonidazole

MISONIDAZOLE, an electron-affinic, nitroheterocyclic compound (1-(2-nitro-1-imidazole)-3 methoxy-2-propanol, Ro-07-0582) is undergoing preliminary clinical trials, which are exploring its capacity to sensitise hypoxic tumour cells to ionising radiation damage¹⁻⁴. The drug also possesses a substantial cytotoxic effect, independent of radiation, which is selectively expressed in hypoxic cells^{5,6}. Both of these properties may contribute to the potential value of this agent as an adjunct to radiation therapy of malignant disease in those situations where radioresistant hypoxic cells represent the limiting factor in achieving local control. It is also possible that the cytotoxic property could be a useful adjunct to chemotherapy as it should be effective against noncycling hypoxic tumour cells. Misonidazole, however, may be cytotoxic to the normal hypoxic tissues in the human body (nerve, skin, cartilage, and so on) and this is a major concern in the clinical application of the drug^{1,4}. Furthermore, misonidazole is metabolised in mammalian cells and at least two products have been isolated⁷, toxic to both aerobic and hypoxic mammalian cells. Thus, if they are able to diffuse freely, the metabolites may also be a threat to aerobic tissues⁸. This cytotoxicity of misonidazole is temperature dependent^{9,10}, and varies with cell line^{11,12}, and cysteamine seems to protect against it¹³. It leads to strand breaks in cellular DNA and those cells which fail to survive also fail to repair these strand breaks¹². In this work we show the effect of ascorbic acid (vitamin C) on the cytotoxicity of misonidazole.

Chinese hamster ovary cells (CHO) were grown in suspension culture according to standard procedures⁵. Growth medium containing the drugs to be tested was de-oxygenated in a stirred glass vessel by flowing purified nitrogen over the solution for 10-15 min before the addition of hypoxic cells (2×10^5 cells ml^{-1}). The flow of nitrogen was maintained throughout the experiment. At the prescribed times, samples were withdrawn from the suspension, diluted, washed and plated in plastic culture dishes for the assay of colony forming ability⁵.

The effect of ascorbate on the hypoxic cytotoxicity of misonidazole is shown in Fig. 1. The toxicity of misonidazole alone in CHO cells is concentration dependent; it shows minimal toxicity to these cells at 5 mM while at 15 mM a 3-h exposure inactivates 95% of the cells. When 5 mM ascorbate is added to either 5 mM or 15 mM misonidazole there is a substantial increase in cell inactivation, although ascorbate alone is nontoxic to hypoxic cells. The

combined treatment of 5 mM ascorbate and 5 mM misonidazole is considerably more toxic than 15 mM misonidazole alone.

In contrast to its effect on hypoxic cells, ascorbic acid is very toxic to aerobic cells^{14,15}. This effect in CHO cells is shown in Fig. 2. Ascorbate oxidation involves one-electron transfer reactions which apparently result in the formation of hydrogen peroxide (H_2O_2) (ref. 16). The addition of catalase, an enzyme which blocks the accumulation of H_2O_2 , completely eliminates the aerobic toxicity of ascorbate to CHO cells. The addition of a nonspecific protein, bovine serum albumin, did not reduce the toxicity (data not shown).

Since ascorbate is an effective reducing agent, the increased toxicity of the combined misonidazole-ascorbate treatment of hypoxic cells could be due to accelerated formation of toxic, reduced metabolites of misonidazole. Alternatively, it might be argued that under hypoxia, misonidazole acts as an oxidant of ascorbate, leading to the formation of H_2O_2 and its resultant toxicity. But, catalase does not reduce the hypoxic toxicity of the misonidazole-ascorbate combination (Fig. 2). Furthermore, when gulonolactone, a nonreducing analogue of ascorbate, was substituted for ascorbate, there was no enhancement of misonidazole toxicity. It seems likely, therefore, that ascorbate promotes the reduction of misonidazole, leading to a greater accumulation of toxic derivatives. Another possible explanation is that, although ascorbate itself is not toxic to hypoxic cells it could somehow be predisposing cells to misonidazole damage. This possibility has not yet been examined.

Fig. 1 Exponentially growing CHO cells were collected from suspension culture by centrifugation and resuspended in growth medium (MEM Alpha, supplemented with 10% foetal calf serum) at 6×10^6 cells ml^{-1} . After maintaining them at this concentration for 10–15 min at room temperature they were added to pre-gassed glass vessels containing growth medium and a prescribed amount of misonidazole and/or ascorbic acid such that the final concentration of cells was 2×10^6 cells ml^{-1} . Drug-medium solutions were freshly prepared before each experiment. The pH was adjusted to approximately 7.3 and solutions were sterile filtered. Purified N_2 , containing less than 5 p.p.m. O_2 , was flowed for 15 min over the stirred solutions at 37 °C before the addition of 1 ml of cells. The flow of N_2 continued throughout the exposure time. At the indicated times 1 ml samples were withdrawn and immediately diluted 10 times in aerobic growth medium at 0 °C. The cells were then washed once and plated for colony formation. Δ , 5 mM misonidazole; \circ , 15 mM misonidazole; \blacktriangle , 5 mM misonidazole plus 5 mM ascorbate; \bullet , 15 mM misonidazole plus 5 mM ascorbate. The error bars represent the s.e.m. values derived from pooled experiments.

Fig. 2 The same procedure was used as described in Fig. 1, except that O_2 was flowed where indicated instead of purified N_2 . \circ , 5 mM ascorbate, O_2 ; \bullet , 5 mM ascorbate plus 0.3 mg ml^{-1} catalase, O_2 ; \blacksquare , 5 mM misonidazole plus 5 mM ascorbate and 0.3 mg ml^{-1} of catalase, N_2 . The dotted line represents the 5 mM misonidazole plus 5 mM ascorbate response in N_2 from Fig. 1. Under N_2 , the presence of catalase (or bovine serum albumin) increased slightly the toxic effects of the misonidazole-ascorbate combination in each experiment.

Several other aspects of this effect of ascorbate have been studied. In order to determine whether the supposed reaction between misonidazole and ascorbate required the presence of cells, ascorbate and misonidazole were added to the growth medium for up to 2 h before addition of cells. This did not change the combined response of Fig. 1, suggesting that the effect is a cell-mediated reaction, and does not occur spontaneously. The enhanced toxicity was found to be strongly temperature dependent. It is more rapid at 42.5 °C and almost absent at 0 °C. Variation of ascorbate concentration at a fixed misonidazole concentration, changes the duration of the initial shoulder seen in Fig. 1, but has little effect on the slope of the exponential portion of the curve. A similar potentiation of misonidazole toxicity was observed in the presence of reduced glutathione, the cofactor in the enzymatic oxidation of ascorbate; however, glutathione was less effective on a molar basis than ascorbate.

The effect of ascorbate and other reducing species (such as glutathione, cysteine, cysteamine) on the hypoxic cytotoxicity of misonidazole clearly requires further examination in order to assess and regulate any possible role in clinical applications. Misonidazole doses used in current clinical protocols result in plasma and tissue concentrations approaching 1 mM¹. The concentration of ascorbate (and perhaps other reducing agents) in the human body can also reach this range¹⁷, where the above *in vitro* studies suggest the occurrence of significant synergistic interactions. Whether the net effect of such interactions might be primarily positive (a contribution to the chemotherapeutic properties of misonidazole) or negative (an enhancement of the drug's cytotoxicity) cannot be predicted. The possibility, however, that such interactions may contribute to the problems of peripheral neuropathy, which have been described in reports of clinical trials of the drug⁴, needs to be explored. *In vivo* studies in experimental animals are a logical next step.

We thank Mrs Isabel Harrison and Mr Spencer Kong for technical assistance. The misonidazole was supplied by Dr C. E. Smithen of Roche Products Ltd. This work was

supported by the BC Cancer Foundation and the National Cancer Institute of Canada. P.D.J. is the holder of a NRC postgraduate scholarship.

Novel treatment for joint inflammation

THE use of liposomes in the entrapment and administration of several therapeutic agents has been described for the treatment of cancer¹ and heavy metal poisoning², and in enzyme replacement therapy³. The advantages of a liposome drug over the use of free or polymer-bound agent are decreased toxicity and degradation, the use of smaller doses and the possibility of targeting the liposome towards a given tissue or site⁴. The localised administration of therapeutic agents, such as the intra-articular injection of cortisol esters in the treatment of rheumatoid arthritis⁵, is a situation where the use of liposomes as a means of providing a stable particulate suspension of entrapped steroid might be used to advantage. This method should reduce considerably the effective dose required to produce relief, and diminish side effects due to escape of steroid from the joint⁶. We report here that the treatment of an acute experimental arthritis in the rabbit with a liposome preparation containing cortisol results in a significant reduction in joint temperature and diameter, whereas treatment with an equivalent amount of cortisol alone, or with liposomes lacking cortisol, does not reduce these two parameters of inflammation.

Old English rabbits (body weight 1.5-2.0 kg) were used throughout the study. A bilateral inflammation of the knee joints was induced by the intra-articular injection of a complex formed from 7.5 mg poly-D-lysine (molecular weight 150,000) and 7.5 mg hyaluronic acid⁷ (both Miles). The initial inflammation induced by the complex is an acute synovitis with fibrin exudation and polymorphonuclear leukocyte infiltration. After 1 week this stage merges with a subacute phase showing macrophage infiltration. At 2-3 weeks after induction the arthritis is fully developed with lymphocytic aggregations, plasma cell infiltration, and the appearance of pannus. Evidence of active chronic inflammation then persists for 3-4 months, after which signs of increased fibrotic scarring occur. This process is normally complete within 7 months.

Infra-red radiation from the surface of the joint and its maximum diameter were used to follow the course of inflammation and to monitor the effect of treatment. The liposome

preparation containing cortisol palmitate was prepared as previously described⁸ using dipalmitoylphosphatidylcholine and egg yolk phosphatidic acid. Control liposome preparations were made by omitting the cortisol palmitate. Control liposomes, liposomes containing cortisol palmitate, or cortisol acetate particles in saline suspension were injected intra-articularly into one joint 4 d after induction of the inflammation. The effect of treatment on joint temperature and diameter was monitored for a period of 3 to 6 d.

Treatment of the experimental arthritis with a liposome preparation containing 35.5 µg cortisol palmitate (equivalent to 20 µg cortisol) resulted in a significant and sustained fall in the temperature (Fig. 1) and the diameter (Fig. 2) of the injected joint. The reduction in both these parameters of inflammation occurred within 24 h and there was no evidence of a contralateral effect in the uninjected joint. Neither injection of a liposome preparation containing 35.5 µg of the palmitate ester of 11- α -cortisol, a stereoisomer of cortisol which has no glucocorticoid activity⁹, nor a control liposome preparation containing no steroid had any effect on temperature or diameter. The injection of control liposomes, or liposomes containing cortisol palmitate into normal rabbit joints did not cause an increase in temperature or diameter, and it was concluded that the preparations were devoid of any inflammatory activity. There have been previous reports of liposomes having biological activity in their own right¹⁰, but the liposomes used in this study seemed to be without activity. The injection of cortisol acetate (equivalent to 20 µg cortisol) in saline suspension did not reduce the temperature or diameter of inflamed joints. Anti-inflammatory activity was seen at much higher doses (equivalent to 0.2-2.0 mg cortisol) and was restricted to a 24 h fall in temperature and diameter, whereas liposomes containing cortisol palmitate produced a sustained (3-5 d) reduction in these parameters of inflammation.

It was shown previously⁸ that cortisol esters are retained in liposomes prepared from dipalmitoylphosphatidylcholine and phosphatidic acid only if there is a hydrophobic anchor.

Fig. 1 Effect of liposomes containing cortisol palmitate on joint temperature. Hair was removed from the joint before the start of the experiment with a commercial depilatory cream. The surface temperature of an area 6 mm in diameter situated laterally over the joint space was measured using a Heimann KT 41 radiation thermometer. The joint surface temperature was allowed to equilibrate with the controlled ambient temperature ($20.5 \pm 0.25^\circ\text{C}$) before measurements were taken. Values are mean \pm s.e.m. of 6 animals. \circ , Treated joint; \bullet , untreated joint.

Fig. 2 Effect of liposomes containing cortisol palmitate on joint diameter. Maximum joint diameter was measured using a Baty spring-loaded micrometer. Values are mean \pm s.e.m. of 6 animals. O, Treated joint; ●, untreated joint.

The demonstration that an injection of cortisol palmitate incorporated into a liposome preparation has a much greater anti-inflammatory activity than an equivalent dose of microcrystalline cortisol acetate, a standard anti-inflammatory steroid ester, validates the use of liposome preparations for local delivery of steroids.

Relationship between haptoglobin and *Streptococcus pyogenes* T4 antigens

DURING a survey of agglutinating activity of human saliva against streptococci¹ we found that saliva from individuals of blood group O agglutinated a particular strain of group G streptococci more often than did serum from those with blood group A or B. When we tested 833 sera we found a dimorphism for antibody-like substances against group G streptococci—sera could be divided into two groups according to their agglutination titre against group G streptococci. The first group had low titres, not rising above 1 : 4 and more usually 1 : 1; the second group had much higher titres ranging from 1 : 200 to 1 : 3,200. There was no overlap between the two groups of sera. We thought that this might be related to a genetic system, probably diallelic. We now report a relationship between the haptoglobin genotype of serum and the streptococcal antigens with which it reacts.

We tested our samples for a wide range of polymorphic blood groups (ABO, MNSs, P₁/P₂, rhesus, K/k, Le^a/Le^b, Duffy and Kidd), serum groups (Gm 1, Gm 2, Gm 4, Hp, Gc), enzyme groups (acP, PGM, ADA, AK, GPT and EsD) and HLA groups (factors of loci Sd¹ and Sd²). All sera without agglutinating activity or with low titres against a particular strain of group G streptococci were of the haptoglobin (Hp) type Hp 1-1. All sera with high titres, however, were of Hp types 2-1 or 2-2. There was no effect due to sex or age.

Further studies showed that sera with the Hp² gene product reacted with *Streptococcus pyogenes* strains carrying the T antigen complex T4/24. This antigen may also be present in some C and G group streptococci and it was only these strains that were agglutinated with high titres by Hp 2-2 and Hp 2-1 sera. In our series 1.4 % of group C streptococci and 6.4 % of group G streptococci carried the T4/24 antigen. A relationship between the T4/24 antigen of streptococci and haptoglobin types has not been described before.

The mechanism of the reaction is unknown but the reacting substance in all human sera is haptoglobin itself. This was demonstrated in cooperation with Dr Uhlenbruck in Cologne, using a purified haptoglobin preparation (98 % purity, Behringwerke, Marburg) which agglutinated the streptococci in the same way. Further evidence was given by a survey of human cord blood samples. If agglutination was negative, haptoglobin could not be detected. Animal sera with Hp 1-1-like patterns (rhesus monkey, rabbit, pig and sheep) did not agglutinate the T4/24 streptococci or did so only to low titres.

Finally, we found that the agglutinating activity of Hp 2-2 or Hp 2-1 sera could be inhibited by the addition of Hp 1-1 serum of human or animal origin before the test. We believe that Hp 1-1 protein represents a form of 'blocking antibody' for the appropriate streptococci.

Partial γ l fragment is a 'natural' bovine IgG1 fragment without detectable class-specific γ determinants

IgG in bovine sera generally consists of a mixture of the two subclasses IgG1 and IgG2. While testing the reliability of the radial immunodiffusion (RID) method for quantifying IgG in bovine body fluids¹, we found a discrepancy. With most sera tested, the combined amounts of IgG1 and IgG2 determined using subclass-specific antisera was equal to the amount of IgG determined with class-specific antisera against γ determinants, that is common to IgG1 and IgG2. But with a few sera the amounts were not equal (unpublished results). (Class-specific antisera against γ determinants were produced by removing antibodies against subclass determinants on immunoabsorbent columns, starting from antisera which contained antibodies against both class ($=\gamma$) and subclass ($=\gamma$ 1 and/or γ 2) determinants.) Using immunoelectrophoretic (IE) analysis, we have now shown that those sera contain a 'fast' IgG component as well as both IgG subclasses. The third component was represented by an arc in the anodic region of the precipitation pattern, and it proved partially identical to that of IgG1 (Fig. 1). Such an arc can be seen in a photograph of IE patterns of sera from calves infected with *Trypanosoma vivax*, although the arc is not mentioned in the report².

Fig. 1 bs+, bovine serum containing Fpyl (6 μ l); bs-, normal bovine serum (6 μ l); Fpyl, partial γ l fragment (24 μ l, 1 mg ml⁻¹); 1, goat anti-bovine IgG1; 2, goat anti-bovine IgG2. The anode is at the top. Arrows indicate reaction of partial identity of Fpyl and IgG1.

The arc in Fig. 1 was produced with antisera against IgG1 that contained antibodies against γ and γ l determinants. When we used antiserum against IgG2 that contained antibodies against L chain, γ 2 and γ determinants, the arc was absent (Fig. 1). The absence of γ determinants and the presence of γ l determinants on the proteins in this arc explained the discrepancy in RID values. The IE arc seemed to represent all or a part of a special kind of IgG1. Therefore, and for reasons explained below, this protein is referred to as partial γ l fragment (Fpyl).

Serum samples containing Fpyl were collected monthly from cows in connection with an investigation into the occurrence of parasitic infections in the field³. They were stored at -20 °C. It was unlikely that 'ageing' of sera gave rise to Fpyl because some freshly collected serum contained Fpyl whereas older serum from the same animals did not. Sometimes serum collected from the same animal in two successive months produced the IE arc, whereas samples collected shortly before and after this period contained little or no Fpyl.

Fig. 2 The concentration of IgG1 was ± 0.1 mg ml⁻¹, and of Fpyl ± 1.0 mg ml⁻¹, anti- γ , goat antiserum specific for IgG class determinants; anti- γ l, goat antiserum specific for IgG1 subclass determinants. Note the reaction of complete identity of IgG1 and Fpyl in the reaction with antiserum specific for γ l determinants and the absence of the precipitation reaction of Fpyl with antiserum specific for γ determinants.

To characterise Fpyl, we isolated it on immunoabsorbent columns⁴ loaded with purified antibodies against γ l determinants (column 1) and γ determinants (column 2). Serum samples containing Fpyl were applied to column 1 and the mixture of Fpyl and IgG1 was eluted with 3M ammonium thiocyanate in phosphate-buffered saline. When this mixture was applied to column 2, only IgG1 was bound.

The protein thus isolated produced an IE arc comparable with the Fpyl arc from the original serum (Fig. 1). In double immunodiffusion (DID), with antiserum specific for γ l determinants Fpyl gave a reaction of complete identity to IgG1 but did not react with four class-specific antisera specific for γ determinants, although these reacted with IgG1. The reaction with one of these antisera is shown in Fig. 2. The isoelectric point of Fpyl, determined by isoelectric focusing⁵, was between 4.4 and 4.7. Estimates of the molecular weight of Fpyl, obtained by gel-filtration using Sephadex G-200 Fine⁶ and electrophoresis in polyacrylamide gel⁷ without reducing agents were 42,000 and 44,000

Fig. 3 Double immunoelectrophoresis patterns of Fpyl with Fc fragment (a) and pFc' fragment (b). The anode is at the top. Note the absence of Fc spurs at the inner side of the Fpyl arcs (arrows in a) and the presence of Fpyl spurs at the inner side of the pFc' arcs, indicating reactions of complete and partial identity, respectively. The splitting of the Fpyl arcs at the inner side of pFc' arcs is brought about by the presence of the pFc' arcs, preventing antibodies against determinants common to pFc' and Fpyl from reaching Fpyl. 1, Goat antiserum against IgG1; 3, bovine serum containing Fpyl; 4, Fc/Fab mixture; 5, pFc'.

respectively. Reduction with 0.1% dithioerythritol, which disassociates the H and L chains of IgG1 (molecular weight 58,000 and 23,500, respectively in polyacrylamide gel) did not affect the value of 44,000 for Fpy1. Therefore we assumed that Fpy1 consists of one polypeptide chain. On the basis of the estimates of molecular weight of Fpy1; the presence of $\gamma 1$ determinants; the absence of detectable L chain determinants, and a decreased concentration of IgG1 in sera containing Fpy1 (see below), we assumed that Fpy1 emanated from an H chain of IgG1. Double immunoelectrophoretic analysis⁸ showed complete identity between Fpy1 and Fc fragment (obtained after digestion of IgG1 with papain⁹) and partial identity between Fpy1 and pFc' fragment (obtained after digestion of IgG1 with pepsin¹⁰) (Fig. 3).

The pFc' fragment includes the complete COOH-terminal part of the H chain (CH3 region) and the Fc fragment approximately covers the combined CH2 and CH3 regions. The molecular weight of Fpy1 (42,000–44,000) accounts for about three-quarters of the estimated molecular weight of an H chain. This molecular weight (58,000) is in fair agreement with estimates of molecular weights of bovine IgG1 H chains reported before (for example, ref. 11). Although the precise location of Fpy1 in the H chain remains to be determined (a small fragment may be missing from one or both sides of the proposed polypeptide chain) Fpy1 probably consists of the combined CH1, CH2 and CH3

Fig. 4 Schematic drawing of the linear structure of IgG1, with an indication of variable (V) and constant (C) regions and the probable position of the Fpy1-fragment (hatched parts).

regions of the heavy chains of the IgG1 molecule (Fig. 4). One may argue instead that part or all of the VH region forms part of Fpy1, so that there are deletions in the H chains as in heavy-chain disease proteins¹². This is unlikely in view of the presence of the CH2 and CH3 regions in Fpy1 and because sera collected shortly before and during the appearance of Fpy1 always contained IgG1 with H chains of normal molecular weight. We assume that this IgG1 is the source of Fpy1, for the concentration of IgG1 is strongly reduced in sera containing Fpy1.

It is surprising that class-specific γ determinants cannot be detected on Fpy1 with either precipitation techniques (IE and DID) or immunoadsorbents. Perhaps γ determinants are more labile than $\gamma 1$ determinants, or they are on the Fd part of IgG1 nearer to the VH/CH1 boundary than $\gamma 1$ determinants, or near interchain disulphide bonds.

We have not detected Fpy1 in hundreds of normal sera, in spite of a supposed continuous catabolism of antibodies directed against various antigens. But Fpy1 appears in sera of cows intentionally infected with *Fasciola hepatica*, and it is likely that the sera in which Fpy1 was found originally were from similarly infected cows. Our results suggest that while antibodies are being bound to antigens of parasitic origin, combined CH1, CH2 and CH3 regions of $\gamma 1$ chains, and presumably CL regions as well, are separated from the rest of the IgG1 molecule, breaking disulphide bonds. Whether CL regions remain intact for some time and appear in Fpy1-positive serum is not known.

The chance of detecting proteins consisting of CL regions only is small in view of the short half-life of light chains¹³. We assume that Fpy1 is generated while the immunological system is confronted with a large antigenic load, leading to, for example, incomplete phagocytosis of the antigen-antibody complexes. It remains to be seen whether Fpy1 arises only in response to parasitic or other corpuscular antigens or whether large amounts of any antigen lead to comparable fragmentation of IgG1. Although fragmentation has been described for Fc- and Fab-like fragments in normal urine¹⁴ and plasma¹⁵, Fpy1 seems to be the first reported catabolic fragment of Ig that is probably related to antigen-antibody interactions *in vivo*.

I thank Mrs Jacqueline J. L. Noordijk and Mrs Willy Stok for technical assistance and Dr L. J. van Tiggele for bovine sera.

Production of HLA antibody in mice immunised with syngeneic mouse-human hybrid cells containing human chromosome 6

XENOIMMUNISATION with human cells or isolated molecules found on the surface of human cells results in the production of antibodies to a variety of human alloantigens (refs 1–3 and unpublished results). The genetic loci which specify the antigens being recognised can then be determined by using rodent-human hybrids containing various human chromosomes as target cells. In this manner, chromosome 11 has been found to include genes coding for a series of antigens designated A_L (refs 1, 4) or HSA-1 (ref. 2) and chromosome 15 to code for β_2 microglobulin⁵. Murine-human somatic cell hybrids with one or a limited number of human chromosomes have been used by us and by others to obtain antisera in mice syngeneic to the mouse parental cells reactive with antigens coded for by

specific human chromosomes^{2,6-7}. The advantage of this method is that antisera generated are specific for the antigen(s) coded for by a particular human chromosome and the reactivity is to a limited number of human cell surface antigens. This allows for both systematic genetic mapping of these antigens and detection of previously unknown cell surface molecules. Chromosome 6 has been shown both by pedigree analysis⁸ and by the use of interspecific somatic cell hybrid target cells⁹ to be the location of the genes coding for the serologically defined antigens (HLA) of the major histocompatibility complex (MHC). We have used a human-mouse somatic cell hybrid containing several human chromosomes, including chromosome 6, to immunise mice syngeneic to the mouse parental cell. The reactivity of the absorbed antiserum has been analysed both serologically and by sodium dodecyl sulphate polyacrylamide gel electrophoresis after immunoprecipitation. Evidence is presented here to show that mice immunised with somatic cell hybrids containing human chromosome 6 produce antibody which reacts with HLA as well as with other human lymphocyte cell surface antigens.

Hybrid cells used for immunisation were the Nude 1 (N 1) cell line¹⁰. This hybrid line was derived from a tumour grown in an athymic mouse injected with hybrid cells obtained by the Sendai virus-mediated fusion of C57B1/6 mouse peritoneal macrophages and LN-SV (an SV40-transformed human cell line derived from skin fibroblasts of a Lesch-Nyhan syndrome patient)¹¹. N 1 was found by isozyme analysis and karyotypic evaluation to contain human chromosomes 6, 7, 14 and 21. Clones containing chromosomes 7, 14 and 21 but not 6 have also been derived from this original hybrid.

The HLA type of human parental cell LN-SV was determined by the standard NIH microcytotoxicity assay in Terasaki plates. These cells were found to express HLA-A2 and HLA-B5 antigens. Clonally derived hybrid cells containing one copy of human chromosome 6 were used to absorb several cytotoxic HLA typing sera, specific for HLA-A2 and HLA-B5. These sera were then tested on a panel of human lymphocytes of known HLA type. Table 1 shows that the hybrid cells containing human chromosome 6 expressed HLA-A2, and were HLA-B5-negative. Hybrid cells without human chromosome 6 (human chromosomes 7, 14, and 21 present) did not absorb out HLA reactivity.

To determine if the murine humoral response to somatic cell hybrids containing human chromosome 6 is to MHC-defined antigens and/or to species-defined antigens, C57B1/6J mice were immunised with N 1 hybrid cells. At 7-10 d after each intraperitoneal injection of $1-3 \times 10^7$ trypsinised cells, mice were bled, and serum was separated and stored at -70°C until use. For these studies, anti-N 1 serum from the sixth immunisation was absorbed with another human-mouse

Fig. 1 Immunoprecipitation of ^{125}I -labelled surface proteins from human lymphocytes with absorbed anti-N 1 serum. Human peripheral blood lymphocytes (isolated from interface of Ficoll-Hypaque gradient (density 1.077) and washed three times with Dulbecco's modified PBS without Ca^{2+} and Mg^{2+} salts) were iodinated (New England Nuclear, NEZ-033H) by the lactoperoxidase-glucose oxidase method as previously described^{12,17}. Extracts were prepared by 1 h incubation (0°C) in 0.1% NP-40, 0.1 M Tris, pH 6.8, 15% glycerol and 2 mM phenyl-methylsulphonyl fluoride (PMSF). Iodinated extracts were incubated for 1 h, 0°C , at a 2:1 ratio with normal human serum from the donor of the lymphocytes or with rabbit anti-human β_2 microglobulin. Immune complexes were cleared from the samples by incubation at 0°C for 1 h with protein A-bearing *Staphylococcus aureus* Cowan 1 strain. Specific serum at a 1:5 final dilution was added to the precleared samples. After incubation at 0°C for 1 h, the immune complexes were absorbed to *S. aureus*, centrifuged and washed. After elution of the absorbed proteins from the bacterial surface (boiling *S. aureus* in 0.1 M Tris, pH 6.8, 15% glycerol, 2 mM PMSF, 2% sodium dodecyl sulphate (SDS) and 1 mM dithiothreitol) the bacteria were removed by centrifugation and the samples applied to 10% SDS-acrylamide gels with 5% stacking gels¹³. Gels were dried onto filter paper and exposed to Kodak NS2T X-ray film. Molecular weight markers for gel calibrations: cytochrome *c* (11,500), myoglobin (17,000), carbonic anhydrase (29,000), aldolase (40,000), catalase (60,000), bovine serum albumin (68,000), phosphorylase A (92,000); a, absorbed anti-N 1 serum, sample precleared with normal human serum; b, normal mouse serum, sample precleared with normal human serum; c, absorbed anti-N 1 serum, sample precleared with rabbit anti-human β_2 microglobulin; d, rabbit anti-human β_2 microglobulin serum, sample precleared with normal human serum.

‡No reaction; lymphocytes do not express this antigen.

hybrid cell line of the same origin containing human chromosomes 7, 14 and 21. Testing revealed that the absorbed anti-N1 serum reacted only with hybrids containing chromosome 6.

To define the cell surface molecules with which the absorbed anti-N 1 serum reacted, we prepared extracts of human peripheral blood lymphocytes which had been enzymatically labelled with ^{125}I using the lactoperoxidase-glucose oxidase method¹². The extracts were reacted with absorbed anti-N 1 serum, or normal mouse serum, and the immune complexes were analysed on 10% polyacrylamide gels¹³. As shown in Fig. 1a, reaction of lysates with absorbed anti-N 1 serum results in precipitation of several proteins; two of these (see arrows) have molecular weights consistent with those of HLA and its associated light chain, β_2 microglobulin¹⁴. No radio-labelled bands are seen when normal mouse serum is used (Fig.

1b). When the extracts were pre-cleared by treatment with rabbit anti-human β_2 microglobulin serum (Dakoimmunoglobulin; Copenhagen, Denmark) (see Fig. 1 legend) and then reacted with anti-N 1 serum, the 47,000 molecular weight (MW) and 12,000 MW bands disappeared, leaving the higher molecular weight proteins coded for by human chromosome 6 (Fig. 1c). Electrophoresis of immune complexes of anti-human β_2 microglobulin serum with the labelled human lymphocytes shows β_2 microglobulin, the 12,000 MW band, and the co-precipitated HLA (Fig. 1d).

Further evidence that the reactivity is to HLA is provided by lysostrip experiments shown in Table 2 (procedure and theory described in refs 15 and 16). Normal human lymphocytes of known HLA specificities after reaction with anti-N 1 are incubated with goat anti-mouse IgG. The cells are then reacted with HLA typing sera. The fact that reactivity to each HLA specificity is affected by this stripping procedure provides evidence that anti-N 1 serum is reacting with HLA molecules on the lymphocyte surface. It is important to note that although HLA-A2 is the only specificity shown to be present on the immunising cell surface, both HLA-A and HLA-B antigens are affected by the stripping procedure. This has been observed with antisera and lymphocytes of other HLA types (data not given). The response seems to be either to a common determinant of HLA molecules or a multiclonal response to many portions of the HLA molecule. If some B cell clones were responding to the private HLA specificities present on the immunising hybrid, they would not be detected because of the overwhelming response to other portions of the molecule. Immunising mice with hybrids containing human chromosome 6 and hybridising B cells from these mice to myeloma cells may result in the constitutive production of monoclonal antibodies specific for the HLA allele(s) of the immunising cell. *In vitro* xenoimmunisation of both human¹⁷ and rat¹⁸ cells with mouse lymphoid cells results in the development of cytotoxic effector cells which are specific for the immunising H2 haplotype. It seems that limited clonal stimulation occurs with the major reactivity limited to the recognition of the allelic specificities of H2.

2.5×10^5 Ficoll-Hypaque-separated human peripheral blood lymphocytes (HLA-A1, 2; B8) were treated with absorbed anti-N 1 serum (or normal mouse serum as control) 1:20, 30 min, 4 °C; treated with goat anti-mouse IgG, 1:5; 30 min, 4 °C, incubated 30 min., 37 °C; treated with goat anti-mouse IgG, 1:5, 30 min, 4 °C; washed three times between each treatment incubated 30 min, 37 °C, and washed twice. Volumes were kept constant at 100 μ l. All washes were with 1 mM HEPES-buffered RPMI 1640 containing 10% foetal bovine serum. Antisera were diluted in 1 mM HEPES-buffered RPMI 1640. This procedure was to 'induce' resistance to antibody-mediated complement-dependent cytotoxicity for the antigen(s) recognised by the anti-N 1 serum. The 'lysostripped' or treated control cells were then tested in an antibody-dependent complement-mediated microcytotoxicity assay to determine whether the cells were resistant to lysis by the indicated sera. (For procedure and discussion of theory, see refs 15 and 16.)

*Sera from Transplantation Immunology Branch, National Institute of Allergy and Infectious Diseases, National Institutes of Health: a, 2-65-9-11-17-08; b, 2-50-6-03-15-03; c, 1-01-7-02-07-02; d, 2-50-6-10-04-01; e, 2-51-2-04-27-01.

†Calculated as follows:

$$\frac{(\% \text{ anti-N 1 treated dead} - \% \text{ c' control dead})}{\% \text{ normal serum treated dead} - \% \text{ c' control dead}} \times 100$$

The test sera used after lysostrip treatment were used at a dilution that killed >60% of the normal serum control; in most cases 80–90% of control cells were killed at the dilution selected.

‡Serum from C57Bl/6 mice immunised with LN-SV human cells.

We suggest that human-mouse hybrid cells containing human chromosome 6 can be used to immunise mice to produce antibodies to the major histocompatibility complex. Additional cell surface molecules coded for by human chromosome 6 are detected with the anti-N 1 sera.

Lymphocyte induced stimulation of human chorionic gonadotrophin production by trophoblastic cells *in vitro*

STIMULATION of target cells following an immunological interaction has been shown to occur under suitable conditions. For example, B lymphocytes undergo blast transformation when cultured in the presence of low levels of anti-immunoglobulin¹, and likewise thyroid cells can be stimulated by LATS (long acting thyroid stimulator) and LATS protector^{2,3}, both of which are immunoglobulins, resulting in increased thyroxine production. There is no evidence that target cells can be stimulated in such a manner after contact with lymphocytes. We present here evidence that increased chorionic gonadotrophin (HCG) production results when trophoblasts are cultured in the presence of maternal lymphocytes.

Trophoblastic cells were obtained from trypsinised fresh placentae and incubated for 1–3 d in Eagle's Dulbecco Modified Medium with 10% foetal calf serum in the presence or absence of lymphocytes. Lymphocytes were obtained from either normal donors, from patients with gynaecological cancer, or from pregnant women at delivery. The lymphocytes were separated on Hypaque-Ficoll and added to the trophoblast cell cultures in the ratio of 1:1 or 5:1. Production of HCG by the cultures was assessed by a radioimmunoassay technique as performed in the section of biochemistry of this hospital.

When trophoblast cells were cultured alone, there was a detectable increase in HCG production after 24 h, followed by a continuous increase over the first 3 d (Table 1). When lymphocytes from normal donors were added to trophoblast cells at a ratio of 5:1 there was slight reduction of hormone production, significant after 3 d ($P < 0.01$, Student *t* test). When lymphocytes from patients with gynaecological cancer were

Table 1 % Increase in HCG production by trophoblast cells cultured in the presence of lymphocytes (mean \pm s.e.m.).

	No. of cultures	Time (Days)			
		0	1	2	3
Trophoblast only	28	100	143.4 \pm 12.9	209.3 \pm 9.6	248.6 \pm 8.7
Trophoblast + normal lymphocytes 5:1	14	100	175.5 \pm 19.4	189.6 \pm 6.1	193.7 \pm 10.3
Trophoblast + maternal lymphocytes 5:1	13	100	164 \pm 8.9	236.5 \pm 7.5	316.5 \pm 16.5
Trophoblast + maternal lymphocytes 1:1	4	100	159.9 \pm 12.8	191.6 \pm 18.7	—
Trophoblast + cancer lymphocytes 5:1	10	100	156.6 \pm 17.5	190.2 \pm 20.3	185 \pm 10
Trophoblast + unrelated maternal lymphocytes 5:1	2	100	—	188	—

added to the trophoblastic cells there was also significant reduction in hormone production only after 3 d ($P < 0.01$). When maternal lymphocytes taken at the time of delivery by Caesarean section were added to the trophoblastic cells at a ratio of 1:1 there was no significant difference, but when the ratio was 5:1 there was a significant increase in the amount of hormone produced after 2d ($P < 0.05$) and 3 d ($P < 0.01$). Comparison of the values obtained from cultures with added normal lymphocytes and those of cultures with added maternal lymphocytes shows a high degree of difference after 2 and 3 d ($P < 0.001$). No stimulation occurred when maternal lymphocytes from unrelated donors were used.

The reduction of HCG production by trophoblastic cells after culture with allogeneic lymphocytes is consistent with the findings of Currie⁴, Douthwaite and Urbach⁵, and Taylor and Hancock⁶, who described lysis of trophoblastic cells by allogeneic leukocytes. This 'allogeneic inhibition' occurs after 24–48 h in culture, and pre-sensitisation of the lymphocytes by target-type antigens is not required. The stimulation of HCG production by maternal lymphocytes is more difficult to explain. This phenomenon may be equivalent to stimulation of target cells by immunoglobulin, as suggested by Rose⁷ for thyroid cell stimulation by lymphoid cells. Further studies are in progress in order to establish whether this phenomenon is in any way altered in abnormal pregnancy, such as pre-eclampsia.

We thank the obstetricians and nursing staff of the Royal Women's Hospital, Melbourne, for placenta and blood samples, and Dr I. Horacek and Staff, Section of Biochemistry of this Hospital, for help with the radioimmunoassay for HCG.

Electrophoretic mobility as a sensitive probe of lectin-lymphocyte interaction

TREATMENT of murine T lymphocytes with concanavalin A (con A) at concentrations as low as 10^{-17} g ml⁻¹ produces significant increases in their electrophoretic mobility. The effect is blocked by α -methyl-D-mannopyranoside (α -MM). Phytohaemagglutinin (PHA) produces similar changes in T-cell mobility while treatment with lipopolysaccharide (LPS), a

B-lymphocyte mitogen, does not. We present here evidence indicating that the altered mobility of con A-treated T cells is due to the rapid release of a factor from the few cells reacting directly with the lectin.

The blast transformation of lymphocytes resulting from treatment with lectins such as con A is of considerable interest since it may serve as a model for the events which occur when lymphocytes are specifically stimulated by antigens. Lectin-induced capping, increased ³H-thymidine uptake and development of blast morphology are relatively slow phenomena. Since the earliest events associated with lymphocyte activation probably occur on the cell membrane within minutes, a technique that would allow immediate assessment of membrane alterations would be extremely useful.

Cell electrophoresis provides a probe of membrane interactions involving changes in the surface charge density, these changes being reflected by an alteration of the cell's electrophoretic mobility¹. Cell electrophoresis has previously been used as a preparative method for separating T and B lymphocyte populations^{2–6}, as a probe for lymphocyte membrane chemical composition⁷ and for studying lymphocyte interaction with a variety of chemical agents including lectins^{8–10}, polynucleotides¹¹, and antisera^{12,13}.

In view of the probable conformational changes in the lymphocyte membrane associated with transformation, it has been suspected that changes in the charge density associated with the membrane would result in an alteration in the electrophoretic mobility of the cell. We have found that extremely low concentrations of con A induce significant increases in the electrophoretic mobility of murine T cells. Moreover, on exposure to con A there is apparently a rapid release of a factor from some murine T cells which induces increased mobility in the remainder of the cells.

Electrophoretic measurements were performed using the technique of Seaman *et al.*¹ in which a suspension of cells in a controlled potential gradient is directly observed through a microscope. The results are expressed in $\mu\text{m s}^{-1}\text{V}^{-1}\text{cm} \pm 1\text{s.e.m.}$ and are based on the time of migration of a series of cells across a fixed number of divisions of an eyepiece graticule. All mobility measurements were carried out at 25 °C in 0.01 M phosphate-buffered saline, pH 7.2, using a microinjection technique to introduce cell suspensions (20–30 μl) into the observation region of the electrophoresis chamber. In most experiments, measurements were collected for 20 different cells, with a reversal of the polarity of the field between measurements. Mobility values of human and murine erythrocytes were -1.08 ± 0.02 and $1.05 \pm 0.02 \mu\text{m s}^{-1}\text{V}^{-1}\text{cm}$ which is in agreement with values reported by others^{1,14}.

Ether-anaesthetised LAF₁ mice (Jackson Laboratories) were killed and their spleens removed. Cell suspensions were prepared and washed three times in 0.01 M phosphate-buffered saline containing 5% heat-inactivated foetal calf serum (PBS-FCS), pH 7.2, by centrifugation at 490 g for 10 min at 4 °C. An enriched T-lymphocyte suspension was prepared by the method of Julius *et al.*¹⁵ using nylon wool columns (Leuko-Pak Leuko-cell Filters, Fenwal Laboratories).

Con A (Miles-Yeda) was obtained as a three-times re-

crystallised powder and a stock solution ($100 \mu\text{g ml}^{-1}$) was prepared by weighing out 10 mg of con A and diluting to 100 ml with PBS. Stock con A solutions were stored at -20°C in 1 ml aliquots. Additional dilutions of con A were made by serial dilutions in PBS. α -Methyl-D-mannopyranoside (Sigma) was dissolved in PBS to yield a concentration of 0.2 M.

Phytohaemagglutinin-P (PHA) and *Salmonella typhimurium* lipopolysaccharide (LPS) (both Difco) were dissolved in distilled water. Stock solutions of PHA (0.1 ml) and LPS ($100 \mu\text{g ml}^{-1}$) were kept frozen at -20°C .

Each experiment was performed by mixing 100 μl of lectin solution or PBS and 100 μl of cell suspension in a test tube and incubating at 37°C for 5 min. Reaction mixtures containing α -methyl mannoside (α -MM) were prepared by adding 100 μl of cells to a mixture of 50 μl of 0.2 M α -MM and 50 μl of lectin solution. In experiments where PHA or LPS were tested, the stock PHA and LPS solutions were diluted with PBS to a concentration of 1 : 1000 and $0.25 \mu\text{g ml}^{-1}$ respectively.

Our initial experiments were performed using con A at final concentrations between 0.1 and $5 \mu\text{g ml}^{-1}$. A significant increase was observed (Fig. 1) in the mobility of T cells treated with con A compared with untreated T cells.

To determine whether this effect depends on con A binding to the lectin-specific carbohydrate moieties on the membrane, we repeated the experiments adding α -MM to the reaction mixture at a final concentration of 0.05 M. This sugar completely eliminated the con A-induced mobility change (Fig. 1). We excluded the possibility that the mere presence of con A in the supporting electrolyte (in contradistinction to its effect on the membrane) led to the changes in mobility. Following incubation of the T cells with con A $0.1 \mu\text{g ml}^{-1}$, we centrifuged the incubation mixture, removed the supernate and resuspended the cells in PBS. The observed mobility of -1.37 agreed well with that of the cells in the presence of the same concentration of con A and suggested that the con A effect is indeed attributable to its binding to the membrane or to induced changes in the membrane. Mitogen-induced increases in the mobility of T cells was also observed with a 1 : 1000 dilution of PHA (-1.35 ± 0.03). However, the B cell mitogen LPS, at a concentration that induces lymphocyte transformation of B cells ($0.05 \mu\text{g ml}^{-1}$) failed to induce a significant change in the mobility (-1.07 ± 0.04) of T cells.

At con A concentrations greater than $5 \mu\text{g ml}^{-1}$, a dose-dependent decrease in T-cell mobility was observed (Fig. 1). This is consistent with observations made in high concentration ranges by other investigators⁸⁻¹⁰. It can be seen (Fig. 1) that at concentrations of 25 and $50 \mu\text{g ml}^{-1}$, the T-cell mobility was actually less than that of the untreated cells. This can be interpreted as the consequence of the physical presence of large numbers of molecules of con A on the cell surface. The fact that at a con A concentration of $25 \mu\text{g ml}^{-1}$, α -MM returned the mobility to untreated levels (Fig. 1) supports this hypothesis.

Fig. 1 Influence of con A on the electrophoretic mobility of murine T lymphocytes. White bars refer to cell mobility in the absence of α -MM and black bars refer to cell mobility in the presence of α -MM. The standard error of the mean is given for the number of measurements indicated above each bar.

Fig. 2 Distributions of mobilities of individual cells treated with various concentrations of con A. Note that at the threshold concentration of $10^{-12} \mu\text{g ml}^{-1}$ of con A the mobility values of individual cells are distributed from control values to the maximum response values.

Furthermore, far from contradicting the results obtained at low concentrations, these data suggest that the increased mobility observed in those experiments can indeed be attributed to induced alteration of the membrane as opposed to the simple presence of a foreign molecule on it. The remaining experiments dealt with this hypothesis.

Decreasing concentrations of con A were incubated with T cells and mobility changes were clearly evident down to a concentration of $10^{-11} \mu\text{g ml}^{-1}$ (Fig. 1). At $10^{-11} \mu\text{g ml}^{-1}$ a maximal increase in electrophoretic mobility was observed with indications that the bulk of the cell population was responding, that is, on observation of the cell population in the electrophoresis apparatus there was no evidence of heterogeneity in the electrophoretic properties of the population. However, at $10^{-12} \mu\text{g ml}^{-1}$ a smaller increase in the mean mobility of the population was observed (-1.19 ± 0.02) and electrophoretic heterogeneity in the population was apparent (Fig. 2). The limited mobility distribution data collected suggested that this lower mean mobility value represented the composite of two cell populations: one consisting of cells with increased mobility and a second characteristic of unaffected cells (Fig. 2). Concentrations of con A below $10^{-12} \mu\text{g ml}^{-1}$ do not induce changes in the mobility of T cells.

The general T cell population response at the threshold con A concentration of $10^{-11} \mu\text{g ml}^{-1}$ was difficult to explain in terms of a direct interaction between lectin molecules and the surface of each lymphocyte in the population. Even if we assume the con A to exist as a monomer having a molecular weight of 27,000, at a threshold concentration of $10^{-11} \mu\text{g ml}^{-1}$, only 220 molecules of con A are necessary to initiate the observed mobility changes in 10^6 T cells. The short incubation time and the few molecules of con A needed to initiate the observed mobility changes suggested that factors distinct from con A binding led to the general T cell response. In order to determine whether con A binding of cells releases a soluble factor(s) which influences the mobility of non-con A binding cells, the following experiment was carried out.

Con A ($10^{-6} \mu\text{g ml}^{-1}$) was incubated with 10^6 T cells for 5 min at 37°C . The cell suspension was centrifuged at 1,000 g for 5 min at room temperature and 50 μl of the supernate was mixed with 50 μl of α -MM (final concentration 0.05 M) and 100 μl of untreated T cells (10^6) was added. This mixture was incubated for 5 min at 37°C and the mean mobility of the cells was -1.30 ± 0.02 . Supernate obtained from $10^{-6} \mu\text{g ml}^{-1}$ con A incubated without T cells for 5 min at 37°C , centrifuged

at 1,000g for 5 min, and added to 10^6 untreated cells in the presence of α -MM had a mean mobility of -1.00 ± 0.02 .

These observations indicate that con A treatment of T cells rapidly induces the release of a factor which can produce an electrophoretic mobility increase in the murine T cell population. Since electrophoresis is sensitive to the charge density on the cell surface, a marked alteration in the cell surface organisation of the T lymphocytes is indicated. Frelinger *et al.*¹⁶ reported that only a small portion of T cells directly respond to con A. They demonstrated that the con A responding T cells were Ia positive and release a factor that can promote the mitogenic response of Ia-negative T cells.

Studies are in progress to clarify the relationship between the factor which induces changes in T-cell mobility and the mitogenic-promoting factor described by Frelinger *et al.*¹⁶ and to establish whether similar electrophoretic responses and factor(s) occur during the interaction of immune T cells with antigens.

Amphetamine induces β -adrenergic receptor supersensitivity

THE interactions of amphetamines and catecholamines in the peripheral sympathetic nervous system and in the brain have been widely studied. Amphetamines have been reported to mimic catecholamines at their receptor sites¹⁻³, inhibit monoamine oxidase⁴, impair reuptake mechanism for the catecholamines⁵ and to directly release catecholamines into the synaptic cleft⁶. Although the consensus of the available literature indicates that *d*-amphetamine indirectly stimulates catecholamine postsynaptic receptors by increasing the release and blocking the reuptake of catecholamines^{7,8}, the question whether dopamine, noradrenaline or both, are of importance for the central actions of *d*-amphetamine is controversial^{7,8}. Recently, α -adrenergic⁹, β -adrenergic¹⁰⁻¹³ and dopaminergic^{14,15} receptors in brain tissue have been successfully identified by measuring the binding of radiolabelled ligands to specific receptor sites. Availability of such methods has permitted the examination of the effects of acute and chronic administration of psychotropic drugs on the postsynaptic catecholaminergic receptors in brain tissue^{13,16}. We report here the effects of acute and chronic

administration of *d*-amphetamine on the postsynaptic β -adrenergic receptors in rat brain.

Specific binding of ^3H -dihydroalprenolol to the brain particulate fractions obtained from control rats and from rats treated with a single dose of *d*-amphetamine (10 mg per kg body weight) was measured. The binding of ^3H -dihydroalprenolol to specific β -adrenergic receptors¹⁰⁻¹³, did not significantly change at 1, 12, 24, 48 and 96 h after administration of a single dose of *d*-amphetamine (results not shown). Thus, acute treatment with *d*-amphetamine did not significantly alter the sensitivity of β -adrenergic receptors in rat brain. To evaluate the effects of chronic treatment with *d*-amphetamine on rat brain β -adrenergic receptors, specific binding of ^3H -dihydroalprenolol was measured 1, 12, 24, 48 and 96 h after the last dose of the drug. Although increased specific binding of ^3H -dihydroalprenolol to rat brain particulate fraction could be seen 1 h after discontinuation of chronic treatment, the increase was not significant when compared to that of control (Fig. 1). Maximal activation of β -adrenergic receptor binding was observed 12 h after cessation of *d*-amphetamine injection. Specific binding of ^3H -dihydroalprenolol at 12, 24, and 48 h after the last injection was significantly greater than that observed in the control preparation. According to Lewander¹⁷, rats remain in a withdrawal state for 4 to 5 d after termination of chronic treatment with amphetamine. Similarly, 96 h after cessation of chronic treatment with *d*-amphetamine, specific ^3H -dihydroalprenolol binding to rat brain particulate fraction

Fig. 1 Effect of chronic administration of *d*-amphetamine on specific binding of ^3H -dihydroalprenolol. The drug was administered intraperitoneally at a dose of 10 mg per kg daily for a period of six weeks. The rats were killed at the indicated times after drug administration by decapitation and the brains were rapidly removed and chilled in ice-cold 0.9% NaCl. The whole brain minus cerebellum was homogenised with a Brinkman Polytron, in 20 volumes of ice-cold 50 mM Tris buffer (pH 8.0 at 25 °C), and centrifuged at 49,000g for 15 min. The pellet was homogenised in the same buffer and centrifuged as before. The pellet was finally resuspended in 50 volumes of 50 mM Tris buffer and used fresh for the binding assay. ^3H -Dihydroalprenolol (32 Ci mmol⁻¹) binding was determined at 25 °C by incubating 0.97 ml of the brain particulate suspension, 2.0 nM ^3H -dihydroalprenolol and sufficient distilled water to make 1 ml as the final volume of the reaction mixture. After 20 min incubation, the reaction mixtures were filtered under reduced pressure through Whatman glass fibre filters (GF/B). The filters were rinsed four times with 4 ml ice-cold Tris buffer to remove most of the unbound radioactive ligand. The filter papers were dried and placed in a counting vial containing 10 ml of scintiverse (Fisher) and counted in a Packard Tri-carb liquid scintillation spectrometer (Model 3380). Corrections were made for nonspecific accumulation of radioactivity by assaying parallel incubations which contained large excess (100 μM) of noradrenaline. Specific binding defined as the difference between total and nonspecific radioactivity was 60-70% of the total radioactive counts. Results shown are averages of nine determinations from three rat brains at each time point, except control where six animals were used. S.E.M. values are indicated by the bars. This experiment has been replicated twice. a, Control; b, 1 h ($P > 0.05$); c, 12 h ($P < 0.001$); d, 24 h ($P < 0.01$); e, 48 h ($P < 0.001$); f, 96 h ($P > 0.05$).

was not significantly different from that obtained with the control preparations (Fig. 1). This would suggest that β -adrenergic receptor supersensitivity may be seen during the withdrawal state following chronic treatment with *d*-amphetamine. Nevertheless, more evidence is needed in support of this possibility.

Both the selective augmentations of motor behaviours in animals and the psychosis in humans associated with chronic amphetamine abuse may reflect a change in catecholaminergic receptor sensitivity. Ellinwood *et al.*¹⁸ proposed that the substantial depletion of catecholamines that accompanies long-term amphetamine treatment allows certain central catecholamine receptors to become supersensitive. This may account for the heightened psychomotor stimulation produced by subsequent injections of amphetamine. The results shown in Fig. 1 are the first biochemical demonstration of the central β -adrenergic receptor supersensitivity after chronic amphetamine intoxication.

Progressive changes in hyperactivity and stereotyped behaviour as a function of the multiple administration of *d*-amphetamine have been considered to be due to the development of reverse tolerance^{19–21}. In guinea pigs²² and in rats²³ readministration of *d*-amphetamine after cessation of daily drug treatment results in a faster onset and also an increase in the intensity of stereotyped behaviour, while administration of apomorphine only affects the faster onset of biological response. Since apomorphine is known to be an agonist of dopamine receptors, these results may suggest that supersensitivity of dopaminergic receptors is related to the decreased latency only and probably does not account for all indices of reversed tolerance. On the other hand, since there is some evidence of involvement of the noradrenergic system in amphetamine induced stereotyped behaviour²⁰, it is suggested that supersensitivity of β -adrenergic receptors may contribute, in part, to the enhancement of the intensity of stereotyped behaviour during chronic amphetamine intoxication.

Thus, chronic treatment with *d*-amphetamine causes a supersensitivity of β -adrenergic receptors in rat brain. This supersensitivity of β -adrenergic receptors may be involved, in part, in the withdrawal reaction to the chronic administration of the drug, tolerance to anorexic effects of amphetamines and enhancement of the intensity of stereotyped behaviour which may lead to psychosis in humans.

This work was supported in part by grants from the US NIH and the AHA, and a postdoctoral fellowship (to V.K.S.) from the Genesee Valley Heart Association.

Antibodies to thaumatin as a model of the sweet taste receptor

In developing a radioimmunoassay for thaumatin, a sweet-tasting plant protein, we have found that antibodies raised against the molecule cross-react with a wide variety of non-protein sweet substances. The results suggest that some structural feature of thaumatin which interacts with the sweet-taste receptor is also the major antigenic determinant. We suggest that antibodies raised against thaumatin may provide a novel method for measuring 'sweetness' *in vitro* and may throw light on the nature of interactions between sweet substances and taste receptors.

Thaumatin occurs in the aril of fruit of the West African plant *Thaumatococcus danielli* (Bentham). Although the sweet properties were first reported in 1855¹, the active principle was not identified as a protein until recently^{2,3}. There are at least two proteins, designated as thaumatins I and II, which differ

Fig. 1 Standard curve for thaumatin using the coated-tube radioimmunoassay. Thaumatin I, extracted and purified by the method of Higginbotham⁴, was used to raise antisera. Three adult male New Zealand white rabbits each received multiple intradermal injections of a total of 4.0 mg of thaumatin in Freund's complete adjuvant. After a single booster injection at 12 weeks suitable antisera were obtained. Purified thaumatin was labelled with ¹²⁵I in a 1:1 molar ratio using either chloramine-T⁵ or lactoperoxidase⁶, both techniques giving satisfactory incorporation. The labelled protein was separated from unreacted iodine by gel filtration using Sephadex G-50 (fine). A solid phase radioimmunoassay was developed with antibody-coated tubes, using a method previously described⁷ for peptide hormones. Antiserum was diluted in 0.05 M carbonate buffer (pH 9.6), 0.3 ml aliquots were placed in 1-ml plastic tubes for 2 h at 4 °C and the tubes were then aspirated, washed and allowed to dry. An antiserum dilution of 1:50,000 deposited sufficient antibody to bind approximately 50% of 3 pg of ¹²⁵I-labelled thaumatin in 200 μ l of 0.02 M citric acid-phosphate buffer (pH 5.8) containing 0.15 M NaCl and 0.1% bovine serum albumin. The assay was carried out at room temperature and the antibody-bound and free labelled thaumatin were separated by aspiration and washing, after incubation overnight. Increasing concentrations of unlabelled thaumatin displaced the binding of labelled thaumatin, as shown. B, Counts bound to antibody, B₀ = counts bound to antibody in the absence of unlabelled thaumatin. Nonspecific binding to 'uncoated' tubes was 0.03.

only slightly in composition and structure. After purification⁴ their sweetness is approximately 2×10^6 times sweeter than sucrose, when compared on a molar basis.

A solid-phase radioimmunoassay procedure was developed, and Fig. 1 illustrates a typical standard curve. The binding of labelled thaumatin to the antibody coated tubes was readily displaced by the addition of unlabelled thaumatin and the nonspecific binding of labelled thaumatin to tubes without antibody was small. The system thus provides a simple and sensitive procedure for the measurement of thaumatin in biochemical studies of this protein or for quality control where thaumatin is used as a food additive in low, palatable concentrations.

The finding that other non-protein sweet substances cross-reacted with the antisera arose by chance when the assay was used with a soft-drink formulation which contained 5.5×10^{-4} M sodium saccharin in the absence of thaumatin and where significant displacement was observed. A wide variety of sweet substances were tested for their ability to displace labelled thaumatin in the assay, including aspartame (1-aspartyl-L-phenylalanyl methyl ester⁸), calcium cyclamate, neohesperidin dihydrochalcone⁹, 4,1¹,6,6¹-Cl₄-galactosucrose¹⁰, 1¹,6,6¹-Cl₃-sucrose¹⁰ and monellin¹¹, the sweet protein from *Dioscorea-phyllum cumminsii* (Diels). All of these sweet substances caused significant displacement in the thaumatin assay (Table 1) but did not produce similar interference when tested at much higher concentrations (up to 20 mg ml⁻¹) in radioimmunoassays for luteinising hormone and corticotrophin.

Evidence that these substances were binding to antibodies raised against thaumatin was obtained when the sweet protein monellin, which has a different amino acid composition and structure from thaumatin, was labelled with ¹²⁵I and tested for binding with different concentrations of the antisera. A maximum of 35% binding was obtained when tubes coated with a 1:1,000 dilution of the antiserum against thaumatin were used to incubate 0.5 pg of labelled monellin. When the same amount of labelled monellin was incubated with the antiserum in solution and ethanol precipitation or a second antibody used to separate the bound from free labelled peptide, even greater binding (up to 85%) was observed with a 1:1,000 dilution of the antiserum and parallel binding curves were obtained with lower concentrations. Furthermore, when ¹²⁵I-labelled thaumatin was incubated with several of the sweet substances tested, including monellin, gel chromatography revealed no aggregation or other molecular transformation which might inhibit binding of thaumatin to the antibody and give the appearance of competitive inhibition.

The extent to which other sweet substances bind to antibodies raised against thaumatin can be expressed as the molar ratios required to produce equivalent displacement of labelled thaumatin in the assay and these values are shown in Table 1. Similarly, the sweetness of these various compounds relative to thaumatin can be derived from the reported values for their sweetness relative to a 10% solution of sucrose which is a

Fig. 2 Regression analysis of the relative sweetness of compounds listed in Table 1 against their immunoreactivity, both plotted on a log scale. Sweetness is expressed as the (log) molar ratio of each substance required to give sweetness equivalent to thaumatin and immunoreactivity as the molar ratio required to give equivalent displacement in the coated tube assay. Key to numbers representing each substance given in Table 1.

conventional standard for such determinations (Table 1). When the immunoreactivity and differential sweetness of these compounds are compared (Fig. 2), the sweeteners are ranked in an almost identical order, with a correlation coefficient value of 0.9606 ($P < 0.001$). It should be noted that sucrose, which is a relatively poor sweetener, will cause displacement of ¹²⁵I-thaumatin from the antibody at high concentrations (50–100 mg ml⁻¹) but at such levels nonspecific effects may influence binding to antibody.

The widely different molecular sizes and chemical structures of the sweet substances which cross-react with antibodies to thaumatin and the excellent correlation between antibody binding and sweet taste suggest that thaumatin has an outstanding structural feature which constitutes the major antigenic determinant and is also the site of interaction with the sweet taste receptor. Thus antibodies raised against this feature will cross-react with other molecules possessing physico-chemical properties which confer sweetness. Interestingly, monellin and aspartame can almost completely displace labelled thaumatin from the antibody at concentrations so low as to almost eliminate the possibility of nonspecific interactions. Although both compounds contain amino acids, the reported sequence of monellin¹² does not suggest that there is a common peptide sequence which is responsible for sweetness.

The remarkable correlation between the recognition of sweet substances by both antibodies and the sweet-taste receptor is probably coincidental but could point to some fundamental relationship in the structure of the recognition site. Binding of sweet substances to antibodies against thaumatin may provide a useful model for the study of interactions at the taste receptor for sweetness and perhaps an *in vitro* procedure for the recognition of novel sweet substances.

Table 1 Comparison of sweet substances

Sweetener	Molecular weight	Relative sweetness		Immunoreactivity
		Relative to 10% sucrose (w/w)	Relative to thaumatin (molar basis)	
(1) Thaumatin	20,000	3,000	1	1
(2) Monellin	10,700	2,000	1/3	2.4×10^3
(3) Neohesperidin dihydrochalcone	642	1,000	1/100	9.0×10^3
(4) 4,1 ¹ ,6,6 ¹ Tetrachlorosucrose*	418	200	1/720	3.0×10^5
(5) L-aspartyl-L-phenylalanyl methyl ester	310	200	1/970	4.0×10^5
(6) 1 ¹ ,6,6 ¹ Trichlorosucrose†	399	100	1/1,500	3.0×10^7
(7) Sodium saccharin	241	150	1/1,600	2.0×10^8
(8) Calcium cyclohexyl sulphamate (cyclamate)	200	50	1/6,000	1.0×10^8

Immunoreactivity is expressed as the molar ratios of each substance required to give equivalent displacement of ¹²⁵I-labelled thaumatin from antibody in the coated tubes assay. Relative sweetness is compared with immunoreactivity in Fig. 2.

* 'Tetrachlorosucrose' is 1¹,6¹-dichloro-1¹,6¹, dideoxy-β-D-fructofuranosyl-4,6 dichloro-4,6 dideoxy-α-D-galactopyranoside.

† 'Trichlorosucrose' is 1¹,6,6¹-trichloro-1¹,6,6¹-trideoxysucrose.

We wonder also whether similar effects could occur with antisera raised against other biologically active substances; for example, could antibodies against the presumed receptor binding site for methionine-enkephalin cross-react with the non-peptide opiate drugs? Such a phenomenon would offer interesting possibilities in screening substances for pharmacological activity.

We thank Mrs Jenny Pennington and Miss Gail Webber for technical assistance, and Professor L. Hough of Queen Elizabeth College, Kensington and Dr R. Khan of Tate & Lyle Group Research and Development for providing samples of the chloro-sucroses.

Phospholipase A inhibition of opiate receptor binding can be reversed by albumin

OPIATE receptors in animal and human brain have been shown to be tightly associated with cell membranes¹⁻³. Our laboratory has reported the solubilisation of an etorphine-receptor complex⁴, but to date it has not been possible to obtain an active receptor in soluble form. Nevertheless, it has been possible to study many biochemical characteristics of the membrane-bound receptor. Its sensitivity to sulphhydryl reagents and a number of other protein reagents^{5,6} as well as to proteolytic enzymes^{1,7} suggests the participation of protein(s) in opiate binding. The evidence is less clear with respect to a function for phospholipids. Opiate binding activity of cell membrane preparations from rat brain has been shown to be exquisitely sensitive to phospholipase A of *Vipera russelli* venom (in the ng ml⁻¹ range)⁸, but very insensitive to phospholipase A present in the venom of *Crotalus adamanteus*¹ or that derived from pig pancreas (Lin & Simon, unpublished). Phospholipase C is inhibitory only in very high concentrations^{1,8}. The great sensitivity of opiate receptors to the Russell's viper enzyme and to ionic and non-ionic detergents^{4,7} points to a possible role for phospholipids in the binding process. We report here that inhibition of opiate binding by phospholipase A can be reversed almost completely by incubation of the enzyme-treated membranes with bovine serum albumin (BSA).

Rat brain membranes were prepared as described previously, with slight modification⁹. Male Sprague-Dawley rats were killed by decapitation. Brains were excised and cerebella were removed. Brains were homogenised in five volumes of 0.05 M Tris-buffer (pH 7.4) with a Brinkmann Polytron, at a power control setting of 5, for two 5-s intervals. The homogenate was centrifuged at 25,000g for 20 min at 4°. The pellet was resuspended in five volumes of 0.32 M sucrose and was stored

at -30° for 2 weeks without any significant loss of opiate binding activity. Frozen homogenate was thawed at room temperature and diluted with 0.05 M Tris buffer (pH 7.4) to give a final dilution of brain tissue of 1 : 60 (w/v).

V. russelli phospholipase A was placed in a boiling water bath for 15 min to destroy any contaminating proteolytic activity. The ability of the phospholipase A to inactivate opiate receptor binding was totally dependent on the presence of calcium⁷. To each reaction mixture CaCl₂ was therefore added at 2 mM concentration. Membranes were incubated with or without phospholipase A (25 ng ml⁻¹) at 37° for 10 min. The reaction was then stopped by chilling the incubate in an ice bath and the enzyme was removed by centrifugation. Phospholipase A-treated and control membranes were resuspended in the same volume of 0.05 M Tris buffer (pH 7.4) with or without 1% BSA. After incubation at 0° for 30 min, the membranes were centrifuged at 27,000g for 10 min, resuspended in the same buffer and centrifuged again. Finally, the pellets were resuspended in the same volume of Tris buffer and stereospecific binding levels of the phospholipase A-treated membranes and their controls were determined as described previously⁸, using an agonist (³H-etorphine), an antagonist (³H-naltrexone) and an endogenous opioid peptide (³H-methionine enkephalin).

The ability of phospholipase A-treated preparations to bind tritiated etorphine, naltrexone or Met-enkephalin was less than 10% that of untreated controls (Table 1). However, the same enzyme-treated membranes after incubation with BSA demonstrated a dramatic recovery of opiate binding activity. As shown in Table 1, binding of all three ligands was now 80-85% of control. Figure 1 shows that fatty acid-poor BSA elicits the same results as non-defatted albumin; other serum albumins, human, porcine, chicken and rabbit, can restore the opiate binding activity of the phospholipase A-treated membranes. Egg albumin was the only albumin tested which did not demonstrate reversal of the effects of phospholipase A. The reason for the lack of restitution of opiate binding by egg albumin is unknown. Of other serum proteins tested, α- and β-globulins demonstrated receptor reactivation of the phospholipase A-treated membranes but γ-globulins were ineffective. We have also incubated trypsin and Pronase-treated membranes with BSA, but restoration of opiate binding activity could not be demonstrated. (Lin & Simon, unpublished). This suggests that the restorative effect of BSA is specific for phospholipase A-treated membranes.

Fatty acids and lysophosphatides, the end products of phospholipolysis have also been shown to be inhibitory to the opiate binding activity of rat brain membranes, but only at relatively high (in the millimolar range) concentrations (Lin & Simon, unpublished). As BSA has been used to remove both

Fig. 1 Restitution of stereospecific opiate binding in phospholipase A-treated rat brain membranes by albumins. Membrane fractions were treated with phospholipase A from *Vipera russelli* venom (11 units per mg protein, Sigma). The procedures of incubation with the albumins are the same as those with BSA described in the text. The determination of stereospecific binding of ³H-etorphine as described in the legend to Table 1. a, no albumin added; b, bovine serum albumin (Pentex, Fraction V); c, bovine fatty acid-poor (Pentex, Fraction V); d, human (Pentex, Fraction V); e, porcine (Sigma, Fraction V); f, chicken (Sigma, Fraction V); g, rabbit (Sigma, Fraction V); h, egg (Sigma, crystallised).

Table 1 Effect of bovine serum albumin on phospholipase A-treated rat brain membranes

Ligand	Phospholipase A	1% BSA	Stereospecific binding (fmol per mg protein)	% of individual control
³ H-etorphine	—	—	136.7	100
	+	—	11.8	8.6
	—	+	126.3	100
	+	+	104.6	82.8
³ H-naltrexone	—	—	139.2	100
	+	—	7.9	5.7
	—	+	134.2	100
	+	+	116.5	86.8
³ H-enkephalin	—	—	61.2	100
	+	—	3.9	6.4
	—	+	78.9	100
	+	+	62.0	78.6

Membrane fractions derived from rat brain were treated with phospholipase A from *Vipera russelli* (11 units per mg protein, Sigma) and incubated with or without BSA (Pentex, Fraction V) as described in the text. Opiate receptor stereospecific binding was assayed by incubation of the phospholipase A-treated and control membranes with 1.1 nM ³H-etorphine (16.5 Ci mmol⁻¹) or 1.8 nM ³H-naltrexone (10.6 Ci mmol⁻¹) with or without 1 μM unlabelled levallorphan at 37° for 15 min. Samples were placed in an ice bath for 10 min before filtration through GF/B filters. ³H-Met-enkephalin (15.9 Ci mmol⁻¹) was used at a concentration of 4.6 nM and incubation was carried out at 4° for 1.5 h with or without 20 μM unlabelled enkephalin.

fatty acids and lysophosphatides from solutions or from membranes¹⁰, the recovery of binding activity following albumin treatment might result from the removal of the end products of phospholipase A hydrolysis. This hypothesis received some support from the observation that the addition of BSA simultaneously with phospholipase A completely prevented the inhibition of opiate receptor activity. However, the inhibition of opiate binding by added lysolecithin or linoleic acid was not restored by treatment with BSA (unpublished results). Nevertheless, an inhibitory effect elicited by the products of phospholipase A hydrolysis cannot be ruled out, because the endogenous fatty acids and lysophosphatides produced within the membrane may have effects on the opiate receptors at much lower concentrations than the exogenous materials, which were added as sonicated suspensions in buffer.

As can be seen in Table 1, the inhibitory effect of phospholipase A on the binding activity of these membranes for tritiated etorphine, naltrexone and Met-enkephalin was similar and their binding was substantially restored by incubation with BSA. These results provide evidence that the binding of agonist, antagonist and endogenous morphine-like material involves the same or similar binding sites.

The remarkable sensitivity of opiate receptors to the phospholipase A of *Vipera russelli* and the reversibility of this inhibition by albumin may provide a useful tool with which to define the role of phospholipids in the stereospecific binding of opiates and endorphins. Moreover, methods for the solubilisation of active opiate receptors may also depend ultimately on the interrelationship of phospholipids and receptor proteins.

We thank Dr P. Elsbach for helpful discussions out of which came the idea to try BSA. This work was supported by grant DA00017 from the National Institute on Drug Abuse. We acknowledge a financial gift from Hoffmann-La Roche, Inc. Nutley, N.J.

Calcium ion-dependent vesicle fusion in the conversion of proalbumin to albumin

PROALBUMIN is the immediate biosynthetic precursor of albumin¹, and has been shown (in the rat) to contain a N-terminal extension (Arg-Gly-Val-Phe-Arg-Arg)^{2,3} which can be cleaved by trypsin to yield albumin. We have recently found an enzyme in rat liver, tentatively identified as cathepsin B (ref. 4), which converts proalbumin to albumin, and which is inhibited 70% by leupeptin (3 μM) and by tosyl-lysyl-chloro-methyl ketone (TLCK, 10 μM). Purified bovine cathepsin B (provided by Dr A. J. Barrett) has also been found to carry out the conversion of proalbumin. Zühlke *et al.*⁵ have discussed the possibility that cathepsin B might catalyse the conversion of proinsulin; and since double basic residues occur at the cleavage points of a number of proproteins, a common enzymatic mechanism might be involved in their conversion for secretion. Our earlier work⁶ suggested that conversion of proalbumin was a very late event in the secretory pathway, which agrees with the suggestion of Ikehara *et al.*⁷ that conversion occurs in Golgi vesicles *in vivo*. Here, we present evidence that conversion takes place in isolated Golgi vesicles *in vitro*, that the enzyme concerned is probably cathepsin B, and that the conversion of proalbumin to albumin involves a Ca²⁺-requiring intracellular vesicle fusion occurring at or beyond a transit step through the Golgi apparatus.

Rats were killed 15 min after intravenous injection with ³H-valine (that is, at a time when labelled albumin would just be emerging from the liver)⁸. Liver Golgi vesicle preparations were made by a modification of the method of Merritt and Morre⁹. The vesicles were found to contain a mixture of radioactive proalbumin and albumin, the proportions of which varied from preparation to preparation and which averaged

Fig. 1 Calcium requirement for conversion of proalbumin to albumin in Golgi vesicles. Golgi vesicles were separated from the livers of two rats⁹, one of which was given 300 μCi ³H-valine 15 min before death. They were finally suspended in 70 mM sucrose containing 1 mM EGTA. Ca²⁺ was added to give the free Ca²⁺ concentration indicated¹¹. The samples were incubated at pH 6.0 (50 mM 2-[N-morpholino] ethanesulphonic acid) with dithiothreitol 1 mM. Final volume 1 ml. Incubation was for 60 min at 30 °C. The reactions were stopped by addition of 200 μl M Tris-HCl, pH 7.8, 50 μl 10% (w/v) sodium deoxycholate, 750 μg unlabelled rat albumin and 5 ml 150 mM NaCl. Albumin and proalbumin were precipitated with anti-rat albumin and separated using ion-exchange chromatography¹⁷ after release from the precipitate².

Fig. 2 Effect of a chemical fusogen on conversion of proalbumin in Golgi vesicles. The preparation of Golgi vesicles was as described in Fig. 1, except that just before the final sedimentation, half the vesicles were treated with an equal volume of 80% (w/v) PEG for 1 min at 20 °C. The remainder were treated in the same way, with an equal volume of 70 mM sucrose. They were then chilled, diluted with 70 mM sucrose and sedimented (100,000g, 20 min). They were suspended and incubated as described in Fig. 1. Ca^{2+} was added to give a concentration of 100 μM . The experiment shown is representative of four similar experiments.

about 70% in the form of proalbumin. The yield was approximately 2–3 mg protein per liver. Our Golgi vesicle preparation appeared by electron microscopy to be predominantly small vesicles, with a few cisternal stacks. Marker enzymes showed contamination by endoplasmic reticulum (5%, glucose-6-phosphatase); plasma membranes (6%, 5' nucleotidase) and lysosomes (8%, cathepsin D). No mitochondrial markers were found. The specific activity of UDP-galactose-*N*-acetylglucosamine galactosyl transferase was increased 50-fold over that of the homogenate. In some experiments, the Golgi vesicle fraction (GF_1) of Ehrenreich *et al.*¹⁰ was also tested. The results were identical in the two preparations.

For the experiments, the vesicles were removed from the gradient, sedimented and suspended in 70 mM sucrose containing 1 mM EGTA. The albumin and proalbumin content was determined by disruption of the vesicles with 0.5% (w/v) deoxycholate and immunoprecipitation using anti-albumin. The proteins were separated by chromatography on DEAE cellulose^{2,17}.

A large and reproducible conversion was observed when the vesicles were incubated at pH 6.0 in the presence of Ca^{2+} , the concentrations of which were maintained as described by Portzehl *et al.*¹¹ (Mg^{2+} did not replace Ca^{2+}). Conversion was inhibited 50% by TLCK (10 μM) and 75% by leupeptin (10 μM added partly free and partly entrapped in multilamellar liposomes). Conversion was completely prevented if the vesicles were pretreated with 1 mM DTT and held at pH 7.2 for 30 min at 30 °C before the incubation at pH 6.0. These experiments suggest that cathepsin B or a similar enzyme was responsible for conversion. There was no loss of radioactive protein during conversion and chromatography revealed the presence only of proalbumin and albumin.

It occurred to us that the substrate (proalbumin) and the converting enzyme might be present in separate populations of vesicles which fuse in a controlled manner (see Novikoff's review¹²), an idea which was reinforced by the report that Golgi vesicles can be induced to fuse in the presence of low concentrations of Ca^{2+} (ref. 13). We therefore undertook experiments with polyethylene glycol (PEG) which has been shown to induce fusion in cells and protoplasts^{14–16}. Golgi vesicles were incubated with 40% (w/v) PEG (molecular weight 6,000) for 60 s at 20 °C, and the fusogen removed by centrifugation. There was a marked stimulation in the conversion of proalbumin to albumin in a subsequent incubation at 30 °C, as shown in Fig. 2.

If the PEG is left in contact with the vesicles, there is complete inhibition of conversion. No Ca^{2+} is required during the pretreatment with PEG, but the subsequent conversion has the

same Ca^{2+} requirement as in the absence of PEG treatment (see Fig. 1).

No conversion was seen in smooth endoplasmic reticulum fractions. A crude Golgi cisternae fraction gave only 30% of the conversion seen in Golgi vesicles separated from the same liver. In the experiments, conversion was shown to be intravesicular. Typically, after incubating 60 min in the absence of Ca^{2+} the albumin contained 6,000 c.p.m. ^3H , whereas with Ca^{2+} 100 μM the figure was 11,000. In the supernatant of both albumin was found containing 2,000 c.p.m. Zero-time controls were identical to samples incubated without Ca^{2+} .

These experiments are compatible with the notion that cathepsin B (or a similar enzyme) converts proalbumin to albumin. It is also reasonable to believe that enzyme and substrate are in separate populations of vesicles which fuse in the presence of Ca^{2+} at or near intracellular concentration.

The results suggest that the fused vesicles form a secretory vesicle, which in turn is able to recognise and fuse with the plasma membrane to allow exocytosis. This would account for the fact that proalbumin is not found in extracellular fluids. The results might also explain the action of colchicine which inhibits the conversion of proalbumin to albumin¹⁷ and of parathyroid hormone (pro-PTH) to PTH¹⁸ as well as blocking the secretion of albumin and PTH, and may therefore have a wide interest.

An unusual interaction between the target of nalidixic acid and novobiocin

BACTERIAL mutation resulting in drug resistance often has pleiotropic effects. Amongst these are alterations in susceptibilities to other drugs. Perhaps the best understood and studied of these interactions are antibiotic resistance mutations that involve genes of ribosomal proteins. The pleiotropic effects induced by ribosomal mutations are usually interpreted by interaction of different ribosomal proteins in the ribosomal organelle. For example, it has been observed that certain ribosomal mutations to neomycin-kanamycin (*nek*) resistance in *Escherichia coli* mask the phenotype of spectinomycin (*spe*) resistance¹. Similarly, there is also interaction between ribosomal ambiguity (*ram*) and the streptomycin (*str*) genes². More recently, it has been observed that there is an interaction of ribosomal (*str*) and RNA polymerase subunit (*rif*) mutations³. I describe here an interaction between mutations involving resistance against two quite different drugs, nalidixic acid and

Fig. 1 Effect of drug combination on the growth of *E. coli* KL161. A series of concentrations of novobiocin in the presence of various concentrations of nalidixic acid were prepared in L broth for the drug sensitivity test. The MIC of each drug combination was determined as described in the legend to Table 1. An isobologram was constructed from these values. Each point on the isobologram represents the two drug concentrations that showed growth inhibition when used in combination.

novobiocin, both of which affect DNA replication. This genetic interaction may reflect existence of a protein complex in the DNA replication machinery which has already been postulated on other grounds (see ref. 4).

Nalidixic acid is an extensively used antibacterial drug whose precise mode of action is poorly understood. The primary action of nalidixic acid is inhibition of DNA synthesis⁶. The structurally unrelated drug, novobiocin, has been shown to inhibit DNA synthesis in a manner similar to that of nalidixic acid⁶. The most likely target of novobiocin seems to be DNA gyrase⁷. Despite a similar action of the two drugs, separate targets seem to be involved, as indicated by the distinct map location of nalidixic acid resistance⁸ and novobiocin resistance⁹ in *E. coli*. The fact that both nalidixic acid and novobiocin specifically block DNA replication suggests a possible *in vivo* interaction between the targets of these two drugs. This possibility was examined with a pair of *E. coli* strains KL161 and KL166. The two strains are isogenic except that KL166 is a *nalA* derivative of KL161¹⁰. First, drug sensitivity tests were carried out, and the results of these tests are shown in Table 1. Note that the *nalA* mutation significantly increased novobiocin sensitivity of strain KL166. This uncommon phenomenon is called collateral sensitivity¹¹. The cause of collateral sensitivity is not clear but drug-target interaction is a possibility. For example, the two drug targets may be structurally or functionally dependent on each other. A mutation in one drug target could thus impair the proper function of the other drug target. This point was further pursued with combination drug testing. It is known that drugs acting on different steps of a biochemical pathway frequently show synergism¹². The results presented in Fig. 1 clearly demonstrate a synergistic effect between the two drugs. Furthermore, in rare cases, drug targets may show such

Table 1 Sensitivity of *E. coli* KL161 and KL166 to nalidixic acid and novobiocin

Strain	MIC ($\mu\text{g ml}^{-1}$)	
	Nalidixic acid	Novobiocin
KL161	5	165
KL166	500	70

Drug sensitivity tested by broth dilution in L broth¹³. KL161 and KL166 were grown in L broth at 37 °C to 10 cells per ml. Approximately 10^8 cells from each strain were distributed into a series of tubes containing various concentrations of nalidixic acid or novobiocin. The lowest drug concentration required to arrest cell growth was designated as minimal inhibitory concentration (MIC) of that drug.

Table 2 Frequency of spontaneous mutation to drug resistance *E. coli* KL161 and KL166

Strain	Frequency of mutation to drug resistance			
	Ampicillin	Chloramphenicol	Streptomycin	Novobiocin
KL161	2.3×10^{-9}	1.8×10^{-4}	3.2×10^{-10}	4030×10^{-6}
KL166	6.5×10^{-9}	2.1×10^{-4}	1.4×10^{-10}	7.9×10^{-5}

Mutation frequency is expressed as the ratio of drug resistant colonies to the number of total viable cells. L broth and L agar were used for cell growth and for plating viable cells. L agar containing antibiotics was used for scoring spontaneously occurred drug resistant mutants. The following drug concentrations were used: ampicillin, $10 \mu\text{g ml}^{-1}$; chloramphenicol, $5 \mu\text{g ml}^{-1}$; streptomycin, $100 \mu\text{g ml}^{-1}$; novobiocin, $200 \mu\text{g ml}^{-1}$ (all drugs from Sigma).

a physical interdependence that an alteration of mutation frequency may result¹. For example, a resistance mutation to one drug could alter the frequency of resistance mutation to a second drug. This was found to be the case. The mutation frequency of the two strains was determined with several antibiotics. The results in Table 2 show that KL161 and KL166 differed in their rate of spontaneous mutation to novobiocin resistance by about 500-fold. This is a specific effect, since the frequency of mutations to ampicillin, chloramphenicol and streptomycin resistance were not significantly altered by the *nalA* mutation (Table 2). Results essentially similar to that of novobiocin were also obtained with coumermycin A₁ (data not shown). This similarity is expected since coumermycin A₁ has been shown to share a common target with novobiocin⁷. It should be noted, that the *nalA* phenotype is not masked by novobiocin resistance. Seventy-four doubly resistant mutants were selected by plating KL166 on novobiocin plates. All mutants retained their resistance to nalidixic acid when replicated on nalidixic acid plates.

Novobiocin and coumermycin have been shown to inhibit DNA gyrase activity and DNA replication in *E. coli*⁷. The precise mechanism of action of nalidixic acid is not known. It is possible that the target of nalidixic acid and that of novobiocin act independently and sequentially in DNA replication. Alternatively, the two drug targets may act interdependently in the replication complex. Taken together with published results on the actions of nalidixic acid and novobiocin, the data presented here strongly suggest that the target of nalidixic acid and novobiocin interact *in vivo*. For example, *nalA* mutation may impose a severe conformational strain on DNA gyrase. Thus, only a limited number of mutations in DNA gyrase are viable. This finding is not entirely surprising since a multicomponent complex is probably involved in DNA replication⁴. A mutation in one component could conceivably affect the function of adjacent components.

I thank J. F. Speyer, P. Sawyer and J. D. Karam for helpful suggestions. This work was supported by the General Medical and Faculty Research Appropriation 1977-78.

Note added in proof: The close relationship between the targets of nalidixic acid and novobiocin is also substantiated by two recent reports^{14,15}.

reviews

Anthropology and aerial warfare

J. Z. Young

From Apes to Warlords. The Autobiography (1904–1946) of Solly Zuckerman. By Solly Zuckerman. Pp. 426. (Hamish Hamilton: London; Harper and Row: New York, 1978.) £7.95; \$17.95.

SCIENTISTS to-day probably associate Solly Zuckerman with Whitehall and the London Zoo. He has indeed served science well in both these places, but in this first volume of his autobiography he tells us about two quite different and earlier Sollys. In the first of these earlier incarnations, he laid the foundations of the knowledge that led to the Pill. In the second, he played a part in devising the strategy of the Royal Air Force. Not being either a gynaecologist or historian, I cannot judge how far these memoirs add new facts to what was already known. But it makes compulsive reading to follow how a young South African made his way into the main streams of anthropology, endocrinology and then, so surprisingly, of aerial warfare.

The significance of the work that he did on monkeys is here almost obscured by the diary of meetings with so many different sorts of people. It is difficult now to believe that before Zuckerman's observation of the swollen behind of the female baboon there was no firm knowledge of the nature of the menstrual cycle. That discovery could indeed be regarded as one of the landmarks of the history of human self-knowledge. Of course, it was not made by one man alone; but Solly's description of the baboons was certainly an important factor, although he modestly refers to it, almost in passing, as "one of several clues".

Out of the wide circle of acquaintances that he made in the 1930s came his life with the warlords. It all began from primitive attempts to find out how to protect people against air raids. He and Desmond Bernal organised themselves into an "Oxford Extra-Mural Unit of the Ministry of Home Security". He gives here literally a blow-by-blow account of how they learned about the effects of bombs on people. This section should be as fascinating for scientists and scientific historians as for soldiers and the general public. Beginning with a few experiments with rabbits and guinea pigs, it ended by contributing essential data for the formulation of the strategy

Zuckerman at Oxford in 1935

At Tobruk in 1943

of vast armies and air forces. The method used at all times was a critical testing of hypotheses. The first one to be disproved was the official Medical Research Council view that blast kills by entering the mouth. Disproved by watching a bird fly away as a great gun fired and then showing that the lungs of a rabbit enclosed up to its neck in a box was not damaged by blast. The same combination of observation and experiment was then applied in the study of the results of bombing, first of one room in a lone raid on Banbury and then of hundreds of incidents at Hull and Birmingham. The results of this survey were the basis of one of the disputes about which much has been written between Tizard and Cherwell. Zuckerman claims that it has never been pointed out that the conclusions Cherwell drew from a preliminary version of their report were exactly the opposite of those reached by the authors of the survey. Unlike Cherwell, Bernal and Zuckerman did not believe that area bombing was effective. As Solly movingly concludes, the final proof came in the bombing of Vietnam where "seven million tons brought no victory—only death and destruction."

It is a fascinating story how this knowledge that they obtained came to

make these two scientists influential in the highest quarters. We have excellent glimpses of Mountbatten and Tedder, of Cherwell and Tizard, of Eisenhower and Churchill, and many more, told, it should be said with a simple directness of observation. Of course, he enjoyed meeting all these great men, but on the whole he kept his head. He has a sharp pen and his views are frank and will not always be welcome. He comments about some of the scientific advisors to Harris at Bomber Command that "not all the scientists who had been drawn into Service posts were as questioning and independent in their judgements as they could have been. On occasion, they were constrained by assumptions which uncannily fitted their master's preconceived ideas".

Among scientists, he has never been partial to anthropologists nor they to him. Nor is he much impressed by philosophers. His comment on Freddie Ayer is that he wishes that he had shown "the interest and energy necessary to become familiar with even a small part of science"; and he doubts "whether the growth of the natural sciences has been much influenced over the past 40 or 50 years by the deliberations of academic philosophers."

On the other hand, he sometimes

At the end of the War, 1945

found it hard to believe in the badness of those about him. In the course of the debate over bombing policy, Zuckerman attended one of the mid-night meetings of the Defence Committee. Churchill read out a minute of Cherwell's describing the suggested bombing plan as "the brain child of a biologist who happened to be passing through the Mediterranean". But in spite of this and other evidence of Cherwell's ill-will and bad judgement Solly could never quite bring himself to recognise what an odious man he was, though he notes that Isaiah Berlin

"used to feel uncomfortable in the presence of the Professor. I never did understand why."

So we are introduced to many of the academics, politicians and soldiers who ruled the world in wartime. It is an invigorating story and shows how necessary it still is to persuade people of the value of applying the scientific method to human affairs. We shall wait eagerly for the post-War sequel. □

J. Z. Young is Emeritus Professor of Anatomy at University College, London, UK.

Current neuropeptide perspectives

Peptides in Neurobiology. Edited by Harold Gainer. Pp. 464. (Plenum: New York and London, 1977.) \$41.40.

THE principal aim of this book, says the Editor in his preface, is to provide a baseline of information and perspectives in the rapidly moving field of neuropeptides. In this aim I believe it succeeds, but it is never easy reading and it provides, in some of its chapters, a plethora of undigested and indigestible information, too much perhaps for even the most dedicated neurobiologist.

There are 14 chapters, by 23 contributors; and the neuropeptides are described, dissected and delimited in four principal, but discontinuous, subdivisions. In order of appearance these are Biochemical Methodology, Localisation and Analysis, Metabolism and Physiology, Pharmacology and Behaviour.

The opening chapter, by Berta Scharrer, is entitled "Historical Introduction". A great deal more than that, it describes, albeit in less than seven pages, the basic concepts of the modern discipline of neuroendocrinology of which the author, together with her late husband, are the undisputed founders. The ancestral neurone "equally endowed for the dispatch of long distance and strictly localised signals" yields to its successor, the neurosecretory neurone, capable of all degrees of variation between neuronal and glandular function. Acknowledgement of the inherent capacity of neuronal elements for hormone production is qualified by the current view that neurosecretory neurones manufacture chemical mediators to a degree greatly surpassing that of the more "conventional" neurones. Is this really true, or has this function in higher neurones

been overlooked because it has not yet been looked for?

The next four chapters (Stein on fluorecamine as a peptide reagent; Straus and Yalow on radioimmunoassay; Sternberger on immunocytochemistry; Leeman, Mroz and Carraway on the isolation of substance P and neurotensin) comprise the main section on "Methodology". Individually excellent, they are not equally germane to the general argument of the work. Usefully set down here, however, they will not need to be repeated when the neuropeptide story is extended by further instalments. Despite editorial denials, there is some degree of overlap in this section.

Brownstein's chapter (6) which follows, begins with some historical aspects of the localisation of neuropeptides and continues with a presentation of the results of microdissection and microassays, particularly as applied to the hypothalamus. Accompanying tables give the quantified distribution of LHRH, TRH, somatostatin, vasopressin and oxytocin.

Next, Reichelt and Edminson append a long list of oligopeptides found in the CNS, discussing their role and ending with the working hypothesis that they represent "the final common pathway of multisignal integration". This exciting but as yet unverified notion gives way to a chapter by Harold Gainer and his associates on the biosynthesis of neurohypophyseal peptides and neurophysin. The work reported concerns the hypothalamo-hypophyseal system of the rat, concentrating on the time course of events by which precursors and peptides are first synthesised and then transported from soma to axon and axon terminal.

A mainly methodological chapter by Marks deals with the conversion of prohormones by specific and non-specific peptidases, and useful lists of the latter are included. This very important field is both lucidly and comprehensively dealt with by the author.

A virtually complete survey of peptides in invertebrate nervous systems

is given by Nora Frontali (with Harold Gainer). The authors conclude that the relative prominence of neurosecretion in invertebrates reflects a paucity of endocrine systems and the lowly phylogenetic position of the neurone. The physiological role of neuropeptides is discussed by Jeffery Barker, and his chapter provides definitions of neurohormone and neurotransmitter, as well as listing the distinctions between them. This is a subject where complete agreement has yet to be reached, but Barker concludes that neurohormonal peptides can cause changes in neuronal membranes which are quite different from those produced by putative neurotransmitters.

The concluding three chapters are written by Cooke (on electrical activity and control of peptide release), Klee (on endogenous opiate peptides), and De Wied and Gispen (on behavioural effects). The first of these, devoted to work on the crustacean X-organ sinus gland neurosecretory system, provides evidence that all peptidergic neurones have full electrical activity. Klee, giving an up-to-date but concise account of the present status of the enkephalins and endorphins, is nevertheless moved to supply an even more up-to-date addendum. This emphasises, if emphasis is needed, the extraordinary rapid pace of enquiry in this branch of neuropeptidology. De Wied and Gispen end the book with a chapter describing their own well-documented studies in rats on the effects (shuttle box avoidance response, grooming, and so on) of the intracerebral exhibition of vasopressin and oxytocin analogues, ACTH and MSH peptides, and fragments thereof. The relationships described are complex, and not to be comprehended in a single reading.

With few exceptions, as has been stated, the individual chapters composing this book are not easy to read and there is an unavoidable lack of continuity between one chapter and another. A great merit of the book is the speed with which it has been published, a result bought at the expense of a superfluity of misprints, including an amusing inversion (p81) where the famous Italian apparatus is ascribed to Gogli.

Despite these minor criticisms, the book represents a valuable exposition of the present status of peptides in neurobiology, and it will do until it is overtaken by events and by its successor.

Experimental Botany: An International Series of Monographs. Volume 13**Plant Response to Wind****J. Grace****December 1977, xli + 204pp., £9.80/\$19.25 0.12.294450.X**

Wind is an important component of the weather as far as crop yield is concerned; for example, it is widely recognised that most crops respond to shelter, but this factor is rarely given sufficient consideration when examining the response of a plant to its environment. This may partly be due to the complexity of equipment required to simulate and examine the effects of wind and also the fact that literature on the subject, until now, has been scattered in journals representing such varied disciplines as botany, forestry, and meteorology. The author brings together this material and discusses shelter effects in terms of the physiology of the plant and the microclimatology of the crop.

Vertebrate Photoreception**edited by H. B. Barlow and P. Fatt****February/March 1978, xvi + 378pp., £14.80/\$29.00 0.12.078950.7**

This volume consists of a collection of papers, the product of a symposium on Photoreception held in London on 2-3 September 1976, under the auspices of the Rank Prize Funds. The subjects covered range from light-induced changes in the visual pigment molecule to the processes operating at synapses in the outer plexiform of the retina, including electrical changes elicited in second-order neurones by activity in photoreceptor cells. Also included is the overall view of visual-signal detection offered by psychophysical studies.

Society for Applied Bacteriology Symposium Series No. 6**Aquatic Microbiology****edited by F. A. Skinner and J. M. Shewan****February/March 1978, xii + 370pp., £15.40/\$30.25 0.12.648030.3**

The field of aquatic microbiology has expanded rapidly in the last decade and the Society for Applied Bacteriology devoted their Summer Conference in 1976 to discussing some of the more important advances which have taken place in this subject. It is intended that this volume, which contains the papers given at the meeting, should provide the practising microbiologist with an up-to-date account of developments in this field. The scope of the book is wide, ranging from the more fundamental aspects of growth and development of microbial communities and their interaction with other organisms, to the practical matters of water purification and supply.

Liquid Metals**An Introduction to the Physics and Chemistry of Metals in the Liquid State****Mitsuo Shimoji****December 1977, xvi + 392pp., £16.50/\$32.35 0.12.641550.1**

This book gives an outline of the present knowledge concerning the properties of liquid metals and alloys. In a liquid metal the conduction electrons are highly mobile, though the order of the ions is lost. In spite of such complicated features considerable progress has been made towards the understanding of liquid metals during the last fifteen years. It is now possible to explain or explore their properties in terms of the quantum theory of electrons in condensed materials and the statistical mechanical theory of classical liquids. Most of the analytical methods used in the book are essentially elementary, and introductory descriptions of the theoretical backgrounds are briefly given.

Development, Function and Evolution of Teeth**edited by P. M. Butler and K. A. Joysey****January 1978, xxii + 524pp., £28.50/\$55.75 0.12.148050.X**

There are perhaps no organs that can be studied in so many different aspects as the teeth. This volume, a synthesis of original research and review articles, is an extensively revised and rearranged version of an important International Symposium on Dental Morphology which was held in Cambridge in 1974. It drew contributions from many disciplines: dental anatomists, anthropologists, embryologists, geneticists, palaeontologists, zoologists and physiologists all gave papers discussing the subject of function, development and evolution of teeth from their own particular viewpoints, and covering the dentition in man and in animals.

Human and other chromosomes

Molecular Structure of Human Chromosomes: Chromosomes in Biology and Medicine. Edited by J. Y. Yunis. Pp. 336. (Academic: New York, San Francisco and London; 1977.) £17.40; \$24.50.

THIS volume emphasises in respect of human chromosomes the recent advances in technology for the study of the eukaryote nucleus. A collection of nine chapters by different authors, eminent in different specialities of the subject, gives a comprehensive cover, even if with some overlapping.

The first three chapters, by Yunis *et al.*, Macaya *et al.* and Steffensen, respectively, deal with the study of human and other chromosomes at the molecular level. The fourth—by Creagan and Ruddle—is on human gene mapping using new methods, particularly by means of man/rodent somatic cell hybrids. This is by far the best chapter of the book for comprehensiveness, clarity, quality of tabulated information, and soundness of deductions. But what has it to do with the title of the book? A further three chapters, by Bahr, Rao and Dutrillaux, respectively, cover mainly the structure of chromosomes at levels between electron and light microscopy. Finally, chapters 8 and 9, by Pearson and Jones, respectively, deal with the comparative chromosomology of primates—the former on the basis of banding patterns and gene homologies, the latter on the basis of the kinds and distributions of repetitive DNAs.

Processing of heterogeneous nuclear RNA, the bulk of which never gets out of the nucleus; chromosomal localisation of specific DNA sequences; human satellite DNAs; human gene localisation using RNA: DNA *in situ* annealing (I dislike the term “hybridisation”) are all treated extensively and competently in the chapters on the molecular level of chromosome organisation. For readers who are not in this field, the treatment illuminates what has been done and how, and what could be done. It is still too soon to draw even a preliminary model on how chromosome structure relates to function.

Chapter 5, by Bahr on “Chromosomes and Chromatin structure”, deals mainly with the 200-Å chromatin fibres, their folding and unfolding, and their relationship to chromomeres, to sister chromatid exchanges and to re-arrangements. The low magnification electron

micrographs are fascinating. To the interpretations one could apply, for the time being, the Italian saying “se son rose fioriranno” (“if there are roses they will bloom”).

Chapter 6, by Rao on premature chromosome condensation, (PCC), shows how an incidental observation made in the early stages of the study of somatic cell fusion led to interesting developments. PCC occurs in the chromosomes of an interphase cell when it fuses with a mitotic cell. It opens the way to the study, in interphase chromosomes, of the distribution of replicating segments and of some aspects of the induction of chromosome aberrations by radiation.

The introduction by Caspersson and his colleagues in 1970 of the banding techniques into human cytology has fostered a flood of major and minor variations: some add to the resolution of the human chromosomes, and others to the confusion. Chapter 7, by Dutrillaux on “New Chromosome Techniques” contributes more to the latter than to the former, in part at least

on account of poor presentation. It does give, however, a good account on the quenching effect of BUdR incorporation on stainability, and its consequences on producing banding patterns, on making sister chromatid exchanges detectable, and so on.

The final two chapters are stimulating, clear, well written and informative. They discuss the light that banding patterns, distributions of homologous genes and distributions of repetitive DNAs throw on primate evolution.

This book is likely to be useful to outsiders or to people working on one approach to human chromosome structure and function, who wish to know something about other approaches. Abundantly obvious is its lack of unity in style, level and coverage, typical of the present plague of multi-author publications based on editorship without dictatorship.

G. Pontecorvo

G. Pontecorvo was on the research staff of the Imperial Cancer Research Fund, London, until his retirement in 1975.

Liquid crystalline state

Liquid Crystals. By S. Chandrasekhar. Pp. 352. (Cambridge University: Cambridge, London and New York, 1977.) £18.

EVERYONE has now heard of liquid crystals and seen a liquid crystal display device. Few know very much about these materials, even physical scientists, although this situation is now changing quite rapidly. The liquid crystalline state of matter is very common—the fact that the number of known examples is not more than several thousand is probably only because more have not been sought or many have not been recognised. The past decade has seen a great upsurge of work in this area, particularly because of the increasing use of the materials in display devices but also because the time was ripe from a purely scientific point of view.

The use of the name liquid crystal is sometimes criticised and the word ‘Mesophase’ is often preferred. The hybrid name, however, is evocative of the mystery and attraction of the materials, but the mongrel offspring is more than simply a half of each parent. Indeed, both the liquid and the crystal aspects of behaviour are strong, but much of the interest and the usefulness of the materials resides in the essentially hybrid properties.

As is usual in a field of research at this stage of development, a variety of textbooks and monographs have recently appeared and there is necessarily some

overlap among them. Professor Chandrasekhar's monograph is a valuable addition to this still small collection. It inevitably invites comparison on the one hand with the introductory textbook by Priestley, Wojtowicz and Sheng, and on the other hand with the elegant and unique monograph on the *Physics of Liquid Crystals* by de Gennes. They all have their place, in that the coverage, approach and level of treatment are significantly different.

Chandrasekhar's book is essentially an extended critical review, primarily of nematics and cholesterics. After a brief introduction (10 pages) there follows a chapter on ‘Statistical Theories of Nematic Order’ (84 pages) and ‘Continuum Theory of the Nematic State’ (89 pages). There is an extensive discussion of Cholesteric Liquid Crystals (88 pages) and the final chapter on Smectic Liquid Crystals is the shortest (47 pages). This deals only with the smectic A and smectic C phases and does not reflect the extent of current interest and activity in the various smectic phases, but perhaps does reflect the current state of detailed understanding of them.

This is a physicist's book rather than a chemist's, and is certainly not one for beginners. One of the difficulties of working in this area is that many disciplines must be brought to bear on a problem and few scientists can be expert enough in all. In this respect Chandrasekhar's book will be a valuable addition to the libraries of those already actively working on liquid crystals as well as those contemplating the adventure.

A. J. Leadbetter

A. J. Leadbetter is Professor of Physical Chemistry at the University of Exeter, UK.

Basic processes in protein biosynthesis

Molecular Mechanisms of Protein Biosynthesis. Edited by Herbert Weissbach and Sidney Pestka. Pp. 720. (Academic: New York and London, 1977.) £39.05; \$55.

In the mid-1960s, the genetic code had been solved and most of the basic processes in protein biosynthesis defined. During the past ten years, knowledge of the detailed mechanisms has grown enormously by contributions from different disciplines and this is reviewed in the collection of 13 articles edited by Weissbach and Pestka.

As Lipmann remarks in his introduction, the pairing of nucleic acid bases represents the driving force in genetic information transfer. The actual mechanism of protein biosynthesis, however, depends to a larger extent on interactions between nucleic acids and proteins. Of the components involved, the structure of only one, transfer RNA, is known. Consequently, ingenious indirect methods have been used to study molecular interactions in protein biosynthesis and many of the chapters are concerned with these.

The complexity of the ribosome, which in *Escherichia coli* is assembled from 54 different proteins and three RNA molecules, poses formidable problems. These are clearly defined in a stimulating article by Kurland, which serves as an essential introduction for many of the other chapters. The use of cross-linking reagents in determining the relative locations of ribosomal components is also discussed here.

Stöffler and Wittmann describe the ribosomal proteins and studies of their location on the ribosomal surface by electron microscopic visualisation of the attachment of antibodies to individual proteins. This very ingenious method is at present somewhat limited by the resolution of the ribosome in the microscope. The statement that "figuratively, the structure of the 30S subunit resembles an embryo or a telephone receiver" is an attempt to convey an impression of the shape, but it underscores certain ambiguities in resolution. Knowledge of ribosome structure may soon improve, probably from studies of crystalline arrays.

More than 200 genes are involved in the specification of the protein synthetic apparatus, and genetic analysis has played a key role in identifying these components. I. Smith gives an excellent discussion of the genetics and control of biosynthesis of the translational system. Pestka contributes a comprehensive review of protein synthesis inhibitors, principally antibiotics. The use of the latter, in conjunction with

genetics and biochemistry, has been the most powerful method in discriminating individual steps in protein biosynthesis. Even in such a complicated system, affinity labelling has been successful in exploring the functional topology of components, and the critical review by Pellegrini and Cantor will interest anyone using these techniques.

Other chapters discuss transfer RNA and synthetases, messenger RNA and individual steps in protein synthesis. Unfortunately, the volume does not include an account of the *in vitro* assembly of the ribosome, which has played an important role in understanding its structural function.

With all this information, it is remarkable that many of the basic mechanisms in protein synthesis still elude us—notably, the fundamental translocation process by which the mRNA moves relative to the ribosome. The answers to this and other questions

depends on a still more difficult task—study of conformational changes in the ribosome.

In their choice of topics, the editors have skilfully encompassed the field. The chapters overlap to some extent, and cross-referencing would have been useful. Because they are simply designated by numbers, the ribosomal proteins are particularly difficult to follow in discussion, and a tabulation of their properties as an appendix would have greatly helped. In most of the chapters the discussion is set in a good conceptual framework although a few are simply reviews.

The book is a unique presentation of the present situation in this complex field and fulfills an essential need for those involved.

J. D. Smith

J. D. Smith is on the staff of the MRC Laboratory of Molecular Biology, Cambridge, UK.

Classic work of modern physics

Quantum Mechanics of One- and Two-Electron Atoms. By Hans A. Bethe and Edwin E. Salpeter. Pp. 369. (Plenum/Rosetta: New York, 1977.) \$8.95.

THIS work by Bethe and Salpeter first appeared in 1956 in the *Encyclopaedia of Physics*, edited by S. Flügge, and was re-issued in 1957 as a separate book published by Springer. The present paperback edition is changed only by the correction of a few misprints and by the addition of new references where they correct actual errors. The publishers describe it, quite correctly, as "one of the classic works of modern physics", and they are to be congratulated on making it available at a very reasonable price.

The theory of the hydrogen atom, in the Schrödinger and Dirac forms, provides one of the exactly soluble problems of quantum mechanics. Comparison of the theory of radiative corrections with precision measurements (Lamb shift) provides crucial tests of quantum electrodynamics. The theory of the helium atom presents problems which are not exactly soluble; treatment of these problems lays the foundations for the development of the theory of many-electron atoms. The work of Bethe and Salpeter is particularly valuable in the discussion of relativistic effects, which are treated in an unsatisfactory way in many textbooks on atomic structures. The book also contains important sections on atoms in external electric and magnetic fields, and on interactions with radiation.

In their preface to the present edition, the authors say that they have

left the book unchanged not because so little has happened, but because so much has happened. This will, I am sure, be welcomed: it is best that there should be no tampering with classics, even by the authors themselves! The book as it stands is of enduring value.

Yet the reviewer is tempted to ask: what *has* happened in the past 20 years? I would say, first, the development of the theory of continuum states of two-electron systems. Bethe and Salpeter do not exclude discussion of continuum states, in that they give a full discussion of the continuum states of hydrogenic atoms and some discussion of photo-ionisation of two electron atoms. There have, however, been major advances in the theory of electron collisions with one-electron atoms, including studies of elastic and inelastic scattering; doubly-excited states which auto-ionise; and very fundamental problems in the theory of electron-impact ionisation, giving two electrons in the continuum. There are also the problems of radiation by one-electron atoms in external fields due to an added electron, that is to say the theory of spectral line broadening by a perturber electron.

Secondly, there are multi-photon problems. Bethe and Salpeter discuss multi-photon processes such as the $H\ 2s \rightarrow 1s$ decay with emission of two photons but not problems, such as the ionisation of atoms by intense coherent radiation fields, which have become of interest due to developments in laser technology.

Who, I wonder, will write reviews of the later developments with a mastery approaching that of the book by Bethe and Salpeter?

M. J. Seaton

M. J. Seaton is Professor of Physics at University College, London, UK.

See what LKB Ultrogel[®] will do for your separations!

LKB Ultrogel[®] is a new kind of gel filtration medium, which now turns gel filtration into a high-resolution technique. High resolution because of the inherent characteristics of Ultrogel: small, rigid, uniform beads with a narrow size-distribution.

When different Ultrogel types are used for serum fractionation, they can do this for you:

Bed dimen.: 1.2 × 55.6 cm
Flow rate: 5.0 cm/h
UV-detection: Curve 1, 280 nm T × 1 Curve 2, 254 nm T × 1

Bed dimen.: 1.2 × 46.8 cm
Flow rate: 5.0 cm/h
UV-detection: Curve 1, 280 nm T × 5 Curve 2, 254 nm T × 5

Bed dimen.: 1.2 × 48.8 cm
Flow rate: 2.6 cm/h
UV-detection: Curve 1, 280 nm T × 5 Curve 2, 254 nm T × 5

Buffer: 0.05M phosphate, pH 7.0, containing 0.171M NaCl and 0.02% NaN₃

Sample: 0.3 ml human serum (70 mg protein/ml)

Uvicord III

monitoring: For AcA 44, 100—0% transmission (T);
for AcA 34 and AcA 22, 100—80% T with automatic switching to 100—0% T

HUMAN SERUM PROTEINS SEPARATED ON LKB ULTROGEL.

IgG and albumin are indicated for the Ultrogel types AcA 44, AcA 34 and AcA 22. It is seen that AcA 44 is the best gel for separating IgG and albumin; with AcA 34 and AcA 22 the separation is reduced.

The void peak (arrowed) in AcA 44, containing proteins much bigger than IgG, is resolved into two peaks on AcA 34, and further resolved into three peaks on AcA 22.

Thus, for separating high-molecular weight proteins, AcA 22 is recommended, whereas AcA 44 is more suitable for fractionation of proteins with molecular weights around 100,000.

Ultrogel type	Effective fractionation range*
AcA 22	100,000 — 1,200,000
AcA 34	20,000 — 350,000
AcA 44	10,000 — 130,000
AcA 54	5 000 — 70 000

* Globular proteins

Ultrogel is a pre-swollen polyacrylamide/agarose gel which can be used straight from the bottle. No time-consuming swelling procedures are needed.

If you really want high resolution in gel filtration, write to the address below for more information, or order Ultrogel directly from the types listed in the table.

newly on the market

Density gradient centrifugation medium. Pharmacia. Percoll is a new medium consisting of silica particles coated with polyvinylpyrrolidone. It produces self-generating gradients on centrifugation, suitable for banding of cells, viruses and subcellular particles. The properties of Percoll include low osmolality and low viscosity; it is completely non-toxic allowing separation of cells and viruses with full viability. Percoll does not penetrate biological membranes permitting accurate determination of buoyant density, and easy removal of media from recovered material. This medium may be re-sterilised by autoclaving without change in properties.

Circle No. 38 on Reader Enquiry Card

Air sampler to monitor bacterial contamination. New Brunswick Scientific. The NBS air sampler uses the slit-to-agar method to detect airborne viable particles. It is designed for automatic operation and can be used with satellite samplers to simultaneously monitor air quality at different locations.

Circle No. 39 on Reader Enquiry Card

Photon counter for spectroscopy. Glen Creston Instruments. The Spex DPC2 photon counting system is designed for use in Raman spectrometers, spectrofluorimeters and other spectroscopic instruments where low light levels are being measured. The unit incorporates a photon counter, a d.c. electrometer and a high voltage supply for a photomultiplier tube. It is computer-ready for additional data processing and automation.

Circle No. 40 on Reader Enquiry Card

Micro-electrode puller. Searle BioScience. The Searle semi-automatic micro-electrode puller is a simple device which relies on gravity to commence the 'pull' when the glass tube, held in a pair of vertically aligned chucks, becomes malleable. As the lower chuck falls it actuates the first of two micro-switches which triggers a solenoid thus accelerating the downward movement. On passing the second microswitch, power to the heating element is cut off.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Cryogenic temperature alarm. Cryotech. The Cryotech TA-2 temperature alarm unit has applications in cryogenics, particularly where it is essential to protect biological specimens against breakdowns in mechanical refrigerators. The unit covers temperatures in the range $+20^{\circ}\text{C}$ to -120°C , with the temperature bandwidth operating over $\pm 2^{\circ}\text{C}$. The TA-2 can be connected to a pressurised dewar and liquid nitrogen pressure system to provide a back-up cooling system.

Circle No. 42 on Reader Enquiry Card

Sampler timer. L.I.P. The L.I.P. Liptronic sampler timer provides infinitely variable wash/sample ratios on auto analysis samplers. The timer features tumbler switches for sample and wash both capable of adjustment from 1-99 seconds with visual indication of function. The unit allows override in either mode.

Circle No. 43 on Reader Enquiry Card

Electrophysiological teaching and research instrument. Searle BioScience. Ceptu (comprehensive electrophysiological teaching unit) is designed for the demonstration and investigation of physiological phenomena such as nerve action potential, conduction velocity and refractory period. The unit measures $53 \times 50 \times 48$ cm. The pre-amplifier stages incorporate a selection

Ceptu from Searle BioScience

of switchable high and low pass filter characteristics allowing response to be tailored to the signal. For single cell work the high impedance probe and capacity neutralisation unit enable cell and micro-electrode impedances to be matched.

Circle No. 44 on Reader Enquiry Card

Ultraviolet measuring system. Pharmacia. Pharmacia Fine Chemicals produce a range of UV-monitors and recorders for detecting proteins, polypeptides, nuclei acids etc. in liquid chromatography. The Dual Path Monitor UV-2 incorporates a flow-cell to allow simultaneous measurement of the absorbance of a flowing liquid at two different path-lengths, 1 and 20 mm. The two independent measuring systems can be operated to measure absorbance or transmission at 254 nm or 280 nm. The one-channel recorder REC-1 and two-channel recorder REC-2 provide a 250 nm recording width, 16 chart speeds and 11 calibrated input ranges with an accuracy of $\pm 0.3\%$ full-scale deflection.

Circle No. 45 on Reader Enquiry Card

Auto sequencer system. Finnigan. The Finnigan Instruments auto sequencer system directs the measurement and the injection of samples into gas-liquid chromatography-mass spectrometer systems. Up to 60 samples can be run unattended. Four 15-vial carousel tray sectors permit reloading without stopping the system for continuous analysis of an unlimited number of samples. The sequencer provides a precise quantitative analysis.

Circle No. 46 on Reader Enquiry Card

Sound level meter. B & K Laboratories. The Type 2210 laboratory reference sound level meter meets the requirements of the proposed type O laboratory reference sound level meter, ensuring improved repeatability when measuring impulsive or fluctuating noise. Automatic gain control provides 90 dB (A) dynamic range on each attenuator setting permitting uninterrupted measurement and recording of a wide range of signal variations. The instrument has a digital display.

Circle No. 47 on Reader Enquiry Card

Digital pH temperature meter. Markson. The solid-state Model 90 digital pH temperature meter measures $28 \times 20 \times 12$ cm. The 0.3-inch high digital LED display includes four switch selectable measurement modes: pH, ATC for automatic temperature compensation on pH measurements, temperature, and millivolts. A $10\text{-}\mu\text{A}$ Karl Fischer current source output is also provided for use in titrations. Measurement ranges are from 0 to 14 pH, 0 to 100°C , and 0 to $\pm 1,999$ mV.

APPOINTMENTS VACANT

UNIVERSITY OF SURREY
DEPARTMENT OF HUMAN
BIOLOGY AND HEALTH
TECHNICIAN GRADE 6
£3,654 to £4,365 p.a.

required as deputy to the Chief Technician and to be responsible under him for the operation of the teaching laboratories of the Department and the day-to-day supervision of a technical staff of six. The laboratories teach physiology, anatomy, and related subjects in human biology to honours degree level.

Applicants (male or female) should possess relevant H.N.C., Advanced City and Guilds Certificate, or similar qualifications, and particularly have considerable experience of this type of laboratory work, with high technological awareness and practical skill. Experience of supervising technicians and an ability to communicate with other groups of staff is also desirable.

Further particulars and an application form for this post may be obtained from the Staff Officer, University of Surrey, Guildford, Surrey, GU2 5XH, or telephone Guildford 71281, ext. 452. 1213(A)

UNIVERSITY OF
GLASGOW
RESEARCH ASSISTANT IN
CLINICAL CHEMISTRY

Applications are invited for the post of Research Assistant in the Department of Pathological Biochemistry, Royal Infirmary, Glasgow (Professor H. G. Morgan). The successful applicant, who will have a good Honours degree in Biochemistry or a closely related subject, will study the effects of various physiological or pharmacological stimuli on the metabolism of human high density lipoproteins. The post is for three years, with a starting salary of £2,904 p.a. The applicant will be encouraged to study for a higher degree (Ph.D.). Applications to: Dr J. Shepherd, Department of Pathological Biochemistry, Royal Infirmary, Glasgow G4 0SF (041-552 3535 ext. 5267), within three weeks of appearance of the advertisement.

In reply please quote Ref. No. 4046M. 1178(A)

The Faculty of Medicine

of the Universiteit van Amsterdam has a vacancy
for the position of

extraordinary full professor of neurobiology (part-time)

The tasks of this professor shall be:

- teaching in one of the fields of neurobiology, in cooperation with other teachers in the neurosciences, including the supervision of students preparing for their Ph.D.
- personal engagement in and supervision of scientific work in the field of neurobiology.

The post of extraordinary professor of neurobiology at the Universiteit van Amsterdam (part-time occupancy for the faculty) has been combined in the past to that of director of the Netherlands Institute for Brain Research, and his scientific work has been performed at that institute. The Institute for Brain Research is a non-university research laboratory directed under supervision of the Netherlands Academy of Sciences, the research performed is now centered around the theme "maturation and adaptation of the nervous system". Applicants for this professorship will also be evaluated for their suitability as director of the Institute for Brain Research (vacant full-time position) by a non-university committee.

Applications should be sent to:

THE CHAIRMAN OF THE FACULTY COMMITTEE,
PROFESSOR J. JAMES,
HISTOLOGICAL LABORATORY,
1e CONST. HUYGENSSTRAAT 20,
AMSTERDAM, THE NETHERLANDS.

1206(A)

RESEARCH ASSOCIATE POSITION

available July 1, 1978. M.S. or Ph.D. in Biochemistry or Cell Biology with research interest in any of the following areas: cell membrane changes in differentiation and malignancy; cell surface membrane synthesis, particularly glycoprotein synthesis; in vitro protein synthesis in mammalian systems; calcium absorption and vitamin D metabolism; vitamin A metabolism. The Research Associate will be part of a new program in Gastrointestinal and Nutritional Research being established at the State University of New York in Buffalo.

An opportunity is also available for qualified applicants for an associated academic appointment in the Department of Biochemistry.

Please send resumé to: Dr Milton M. Weiser, Chief of GI and Nutrition, SUNY at Buffalo, c/o GI Laboratories, Massachusetts General Hospital, Boston, MA 02114.

Affirmative Action/Equal Opportunity Employer. 1218(A)

M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
Watford Road, Harrow, Middlesex, HA1 3UJ

The division of psychiatry require a

CLINICAL OR NON-CLINICAL SCIENTIST

with an interest in neurochemical aspects of psychiatric disease and with expertise or special interest in one of the following fields:—

1. Neuropeptides
2. Post-mortem neurochemical studies
3. The clinical pharmacology of psychotropic drugs

Salary will be on the M.R.C. clinical or non-clinical scales of £4,152 to £6,279 p.a. and £3,995 to £6,655 p.a. plus appropriate London allowance.

The appointment will be for a period of three years and non-clinical graduates must have three years experience.

Application forms available from Mrs J. Tucker-Bull and candidates may visit the division by contacting Mrs P. Wright on 01-864 5311, ext. 2752. Closing date: February 25. Please quote Ref. 125/1/A26. 1214(A)

INTERNATIONAL LIVESTOCK CENTRE FOR AFRICA

ANNOUNCEMENT OF VACANCIES

Titles of posts: Programme Leader; Forage Agronomist
Country of assignment: Ethiopia
Duty Station: Addis Ababa
Duration of assignment: Two years, the first year being a probationary period; possibilities of renewal.
Closing date: March 31, 1978
Date of recruitment: June 1, 1978

The International Livestock Centre for Africa is establishing as one of its activities, a research programme on livestock production in the Highlands of Africa. This programme aims at developing farming systems in which livestock contribute more to the total farming system and income of the farmers. The focus is peasant farming: improvement of dairy and sheep production and animal traction are some of the components in this study, with improved fodder production as one of the main approaches.

PROGRAMME LEADER

Under the responsibility of the Director or his designate the incumbent will:
 — direct a multidisciplinary research team involved in the development of more efficient livestock production systems in the Highlands of Africa.
 — advise in the design and implementation of national efforts in the same field.

Qualifications: Advanced university degree, preferably in Animal Science or Forage Agronomy.
 Minimum of 8 years experience in Africa in, for example, small holder settlement schemes.

FORAGE AGRONOMIST

Under the responsibility of the Programme Leader, the incumbent will:
 — select suitable fodder species for the various environments of the Highlands and evaluate those species under experimental and farm conditions.
 — participate with scientists of other disciplines in the development of better farming in these environments.

Qualifications: Advanced university degree in Agronomy, preferably with knowledge of Animal Nutrition.
 Minimum of 3 years experience in forage production research under similar conditions.

Salary and Benefits: According to experience and qualifications, under a system similar to that in use by the United Nations.

Both candidates are expected to be fluent in English with a good working knowledge of French.

Applications, including full curricula vitae and details of published work, should be forwarded to:

The Director
 ILCA
 P.O. Box 5689
 ADDIS ABABA
 Ethiopia

1223(A)

THE UNIVERSITY OF MANCHESTER RESEARCH ASSOCIATE IN GERIATRIC MEDICINE

Applications are invited for this post, tenable until November 1979, in the University Department of Geriatric Medicine at Withington Hospital within the Geigy Unit for Research in Aging. The work of this Unit is to carry out research into the biology of the aging process. A postdoctoral biochemist, preferably with experience in protein or connective tissue biochemistry, is required to carry out a project concerned with age-related changes in the composition of the specialised connective tissues, basement membranes. Salary up to £3,975 p.a. Applications including curriculum vitae and the names of two referees should be sent as soon as possible to Dr J. D. Schofield, Geigy Unit, Department of Geriatric Medicine, University Hospital of South Manchester, Manchester M20 8LR.

1131(A)

UNIVERSITY OF BATH BIOCHEMISTRY DEPARTMENT EXPERIMENTAL OFFICER

Applications are invited for the post of Experimental Officer in a team studying the immunochemistry of the acetylcholine receptor protein at the vertebrate neuromuscular junction, financed by the M.R.C. The appointee will have responsibility for establishing and maintaining chicken embryo muscle cells in culture in order to study the acetylcholine receptor on such cells. Experience in tissue culture techniques will be an advantage.

The appointment will be for three years from April 1, 1978.

Commencing salary, £2,955 per annum.

Further particulars and application forms may be obtained from the Personnel Officer, University of Bath, Claverton Down, Bath, quoting reference number 78/14/N. Closing date will be Monday, February 13, 1978.

1154(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of PROFESSOR in the Department of Veterinary Anatomy. Applicants should preferably be holders of a first Veterinary of medical professional degree, plus a Ph.D. in one of the following areas: gross Anatomy, Developmental Anatomy, Histology and Embryology. They must also have a considerable teaching and research experience at the University level. The appointee would be required to teach Veterinary and Agriculture under-graduate students, as well as train postgraduate students as well as do research in his/her specific field of specialisation. Familiarity with electron microscopy and a variety of histological techniques would be an advantage. Salary scale: K£4,632 to K£5,562 p.a. (K£1=£1.31 sterling). The British Government may supplement salary by £4,674 p.a. (sterling) for married appointee and £3,384 p.a. (sterling) for single appointee (supplements are reviewed annually and are normally free of all tax) and provide childrens education allowances and holiday visit passages. Terms of service include family passages: superannuation: medical aid scheme: regular overseas leave and various allowances. Detailed applications (2 copies) including curriculum vitae and naming 3 referees should be sent airmail by February 22, 1978 to Registrar (Recruitment and Training) University of Nairobi, P.O. Box 30197, Nairobi, Kenya. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

1183(A)

UNIVERSITY OF SYDNEY LECTURESHIP/SENIOR LECTURESHIP IN PHYSIOLOGY

The appointee will be required to teach courses to Medical, Science, Pharmacy and Dental students and expected to carry out research in some branch of Physiology, preferably in the area of Gastrointestinal Physiology or Endocrinology. Candidates should have a Ph.D. in Physiology, M.D. or other equivalent higher degree; preference will be given to a candidate with medical qualifications.

The position is permanent but may be filled for three years in the first instance with the possibility of permanency during that time, or in certain cases return fares. (If a suitably qualified candidate with expertise in the indicated research areas is not available a fixed-term contract may be offered to an appropriately experienced Physiologist in another branch of the discipline.)

Salary Range: Lecturers \$A14,851 to \$19,551 p.a. Senior Lecturers \$A19,971 to \$23,299 p.a. Where appropriate a pre-clinical loading will be payable to a medically qualified appointee.

Applications including curriculum vitae, list of publications and names of three referees by February 28, 1978, to Registrar, University of Sydney, NSW 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

1198(A)

UNIVERSITY OF IDAHO

Assistant or Associate Professor/Ornamental Horticulturist, University of Idaho. Responsibilities: approximately 80% teaching, 20% research. Ph.D. required. Position available after July 1, 1978. Position open until acceptable candidate is selected. Inquiries should be sent to: Ornamental Horticulture Position, Dept. of Plant & Soil Sciences, University of Idaho, Moscow, Idaho 83843. (Ph. 208/885-6276. A.A./E.O. employer and educational institution.

1148(A)

KINGSTON POLYTECHNIC SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES SENIOR TECHNICIAN

to be responsible for the efficient running of an Applied Chemistry laboratory. This is an important laboratory within the School and requires a person with initiative to carry out the large range of duties required using the specialised equipment. Besides a knowledge of chemical engineering equipment, a knowledge of machine-shop practice is necessary as the technician would be responsible for a small mechanical workshop attached to the laboratory. It is also an important part of the post to develop and build equipment necessary to carry out the teaching and research programmes. Duties include maintenance and servicing of equipment plus general duties within the laboratory.

£2,922 to £3,702 plus £312 supplement plus stage 2 supplement plus £285 London allowance.

TECHNICIAN

to be responsible for a postgraduate research laboratory. An interesting post with a wide variety of duties. It is expected that the applicant will have at least 'A' level chemistry and be able to assist both research students and staff in various applications of their research. Other duties include maintenance and servicing of laboratory equipment plus general duties. Day release available.

£1,215 to £2,529 and £312 supplement and stage 2 supplement and £285 London allowance.

Further details and application forms from Assistant Registrar (Personnel), Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel: 01-549 1366.

1211(A)

Meteorological Office, Bracknell

FLUID DYNAMICIST

for theoretical studies
of the atmosphere

This is an opportunity to join a small team led by Dr Raymond Hide, FRS, investigating the basic principles controlling the motions within rotating fluids.

The person appointed will undertake theoretical studies related to experimental work on the structure, stability and non-linear interactions of various types of wave motions and associated work on atmosphere predictability.

Candidates must be theoretical fluid dynamicists with a 1st or 2nd class honours degree in applied mathematics or theoretical physics. They must also have at least 2 years postgraduate research experience and be able to show evidence of high ability in research. Appointment will be for 3 years as a Junior Research Fellow or Senior Research Fellow, according to experience, with a salary between £3,375 and £5,675.

For further details and an application form (to be returned by 3rd March 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants. RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: S/9670.

1166 (A)

MINISTRY OF OVERSEAS
DEVELOPMENT
TROPICAL PRODUCTS INSTITUTE
FRUIT AND VEGETABLE
MARKETING
TECHNOLOGIST

Applications are invited for a scientist to work on marketing technology of fresh fruits and vegetables, including root crops, produced in developing countries. Applicants must be willing to undertake long-term overseas assignments of one year or more, or short-term visits up to four months. Assignments or visits may involve Research & Development work on crop handling and storage and advisory work on market management and design. It is envisaged that this will be a period appointment of three years. The post will be graded Senior Scientific Officer or Higher Scientific Officer with a salary in the range £4,185 to £5,778 for Senior Scientific Officer and £3,254 to £4,454 for Higher Scientific Officer plus £465 Inner London Weighting and Phase 1 & 2 supplements to pay of £522 per annum. Applicants should have a degree in agriculture or a related science and at least five years postgraduate experience for S.S.O. and 2 years for H.S.O. preferably in horticultural crop handling or production. The appointee will work a 41-hour week including meal breaks with 22 days annual leave per year plus 10½ Public and Privilege holidays. The post will be pensionable.

Application forms from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB. 1172(A)

UNIVERSITY OF
NOTTINGHAM
DEPARTMENT OF ZOOLOGY
LECTURER IN ZOOLOGY

Applications are invited for the above post. Preference will be given to applicants with research interests in either Immunology or Developmental Biology, although applications from candidates suitably qualified in other branches of Zoology will be considered. The appointment will preferably take place from April 1, 1978, although consideration will be given to applicants unable to start before October 1, 1978. The starting salary will be in the range £3,333 to £3,761 per annum.

Further details and application forms returnable not later than February 13, 1978, are available from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. No. 543. 1160(A)

UNIVERSITY OF
DUNDEE
DEPARTMENT OF
BIOLOGICAL SCIENCES
LECTURESHIP

Applications are invited for a Lectureship in the above department from persons with an interest in any field of Plant Biology other than nitrogen metabolism and photosynthetic prokaryotes.

Salary on the scale £3,333 to £6,655 (currently under review) with initial placing dependent on qualifications and experience. Superannuation under U.S.S. Grant towards removal expenses to Dundee.

Applications (6 copies: overseas applicants 1 copy) quoting Reference EST/17/78J and naming three referees should be lodged by February 23, 1978 with The Secretary, The University, Dundee DD1 4HN, from whom further particulars may be obtained. 1188(A)

Senior Registration Officer (Pharmaceutical)

Our Research Department requires a Senior Registration Officer to register the company's own pharmaceutical products. The person appointed will be responsible for the supervision of a team of officers registering our products and preparing submissions on an international basis. He/she will be expected to contribute to the preparation of drug development programmes and to deputise for the Head of Product Registration when required.

The position will be suitable for a graduate, between 25 and 35 years of age, with 3 to 4 years experience of drug registration and seeking to develop a career in the industry.

The company operates a profit earning bonus scheme, contributory pension scheme and provides help with relocation to the Nottingham area if appropriate.

Please send for application form to: T. W. Flower, Employment Manager (Technical) (U),

The Boots Company Ltd.,
Station Street, Nottingham, NG2 3AA.

1212(A)

UNIVERSITY OF
ABERDEEN
DEPARTMENT OF ZOOLOGY
RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant (M.R.C. supported) to examine the relationship between surface-bound antibody and nutrient absorption in tapeworms. Candidates should have an Honours Degree either in Immunology or in Biochemistry (with experience in immunological techniques).

The appointment will be tenable for three years from a date to be arranged as soon as possible, at an initial salary of £2,904 per annum (plus superannuation benefits).

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by February 17, 1978. 1142(A)

THE UNIVERSITY
OF LEEDS
DEPARTMENT
OF PHYSIOLOGY

Applications are invited for a LECTURESHIP in Physiology. The Department teaches Science, Medical and Dental students, and has research interests in the major fields of mammalian physiology. Medical qualification valuable but not essential.

Salary on the lecturer scale £3,333 to £6,655.

Applications should be returned to the Registrar, The University, Leeds LS2 9JT, quoting reference number 104/4/D, from whom further details are available. Closing date for applications February 20, 1978. Informal enquiries may be addressed to Professor G. R. Hervey, Department of Physiology. 1168(A)

MEDICAL RESEARCH
COUNCIL

Cellular Immunology Unit
University of Oxford

A vacancy exists for a postdoctoral scientist experienced in

TISSUE CULTURE

The Cellular Immunology Unit is studying functional subsets of lymphocytes and their stem cells and the biochemical nature of their cell-surface molecules. Applicants should be interested in studying the function of cell surface molecules using *in vitro* culture techniques, and also in the production of antibodies by cell fusion.

The initial appointment is likely to be for a 3 year contract on the M.R.C. non-clinical scientific staff with a salary on the appropriate point in the Grade 11 scale (£3,333 to £5,219; under review). Starting date, October 1, 1978 or by agreement.

Applicants should send a curriculum vitae and the names of two referees to Dr A. F. Williams, M.R.C. Cellular Immunology Unit, Sir William Dunn School of Pathology, University of Oxford, Oxford OX1 3RE, U.K. 1137(A)

MERSEYSIDE COUNTY COUNCIL
ASSISTANT KEEPER (PHYSICAL SCIENCES)

£3,395 to £4,214 p.a. including supplements

Applications are invited for the post of Assistant Keeper (Physical Sciences) based at the County Museum, Liverpool. Applicants should possess a degree in an appropriate subject, or the Museums Association Diploma. The successful candidate will have special responsibilities for the operation of the Museum Planetarium and will have particular interests in astronomy. Experience of museum work or work in an associated field is desirable.

Application forms, returnable by February 17, 1978, and further particulars from the Director, Merseyside County Museums, William Brown Street, Liverpool L3 8EN. (Tel: 051-207 0001). 1169(A)

GREATER GLASGOW
HEALTH BOARD—
EASTERN DISTRICT
MEDICAL LABORATORY
TECHNICIAN

Glasgow Royal Infirmary,
Glasgow G4 0SF

A vacancy exists in the University Department of Medicine to co-operate in a team carrying out research on aspects of Thrombosis and Haemostasis. Previous experience is not essential. Applications to the Administrator with names and addresses of two referees. 1189(A)

Biostatistician

The Syntex Research Centre located on the campus of Heriot-Watt University just west of Edinburgh carries out research in pharmacology, toxicology, pharmaceutical development, metabolism and supervision of clinical studies.

SYNTEX
Research Centre

The work is conducted in an innovative and creative atmosphere on a new purpose-built site.

There is now a vacancy for a Biostatistician to provide specialist advice and assistance on the design and subsequent results/analysis of clinical trials and other biological experiments.

Together with an appropriate degree or professional qualification, you will be experienced in the statistical techniques involved in this field, with the ability to relate to other people in a practical, no-nonsense environment. The capability to devise and operate computer analyses would be highly desirable. Age—late 20s upwards.

Salaries and fringe benefits with the company are attractive and relate directly to experience and background.

Please contact: **NICK TEMPLEMAN, PER,**
127 George Street,
Edinburgh 031-225 2736.

1173(A)

LAKEHEAD UNIVERSITY

Thunder Bay, Ontario, Canada

A position is available for a Post-doctoral Fellow or a Research Associate to investigate the interaction of tetrahydroborate ion with transition metal systems. The position is available immediately and the salary will be in the range \$10,500 to \$13,000 p.a. according to qualifications and experience. Applications, quoting the names of three referees, should be sent to:—

Dr D. G. Holah
Department of Chemistry
Lakehead University
Lakehead University
Canada P7B 5E1.

1147(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL

DEPARTMENT OF MEDICINE
TECHNICIAN

required for Rheumatology Unit as soon as possible until August 1979 to undertake routine and research work involved with Immunological studies of the connective tissue diseases. Minimum qualifications H.N.C. or equivalent, salary up to £4,121 per annum.

Application forms from Personnel Officer, R.P.M.S., 150 Du Cane Road, London W12 quoting Ref. No. 2/360/N. 1135(A)

FIELD STUDIES COUNCIL

WARDEN/DIRECTOR
OF STUDIES

required at Juniper Hall Field Centre, Dorking, Surrey. Good degree in biology or other relevant field science, educ. qualis. desirable. Administrative and field teaching experience essential. Duties include full responsibility for running Centre (staff, finance, academic work etc.) with share of teaching; research opportunities. Present salary scale (under review) £3,480 by £102 by £102 by £99 by £252 by £252 by £246 to £4,533 plus free board and lodging (married accommodation).

Juniper Hall is a gateway to the English landscape, sited in classic field-work region of North Downs and Weald, close to London. Opportunity for person with initiative and new ideas, including more courses for students from Western Europe (present Warden's new post will include overseas recruitment duties). Appointment summer 1978 or sooner, applications must be in by January 30 (weekend interview mid-February), forms and details from Director J. W., Field Studies Council, Preston Montford, Montford Bridge, Shrewsbury SY4 1HW. 1141(A)

INTERNATIONAL LIVESTOCK CENTRE FOR AFRICA

One of the international research institutes funded by the Consultative Group on International Agricultural Research, is expanding information and Training Services and invites applications from qualified and experienced personnel in

- Agriculture Training
- Conference Administration
- Editorial Services
- Library Management
- Publications
- Scientific Translation (English — French — English)

The majority of the staff to be recruited will be based in Addis Ababa, Ethiopia, though some can expect to be based at regional centres in Nairobi, Kenya and Bamako, Mali. Some staff members are required to direct activities in the field of information and training, while others are required to fulfill specific functions within the areas listed. Salaries will vary according to post and experience, but are generally competitive in the range of US \$10,000—32,200 per annum. An outstanding applicant, appointed to a position of wide responsibility, could be offered a salary exceeding US \$32,200 per annum. Most international staff in ILCA are required to be bilingual in English and French.

Most appointments will be made on a two year contract, though applications from those wishing a short term contract (6 or 12 months) are also invited. Applications should be submitted in writing to:

Director
ILCA
P.O. Box 5689
Addis Ababa
Ethiopia

to arrive before 28 February (quoting ref. ITS).

THE UNIVERSITY OF LEEDS

DEPARTMENT OF
BIOCHEMISTRY

Applications are invited for the post of

LECTURER

in the above Department. The person appointed will participate in teaching biochemistry to science and to medical students. Facilities and opportunities for research are excellent. The appointment will date from October 1, 1978. Salary on the lecturer scale £3,333 to £6,655.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/10/D. Closing date for applications March 10, 1978. 1162(A)

HEAD

DEPARTMENT OF GEOLOGY UNIVERSITY OF ILLINOIS at URBANA-CHAMPAIGN

The Department of Geology of the University of Illinois at Urbana-Champaign invites applications for the position of Head of the Department of Geology. Candidates should have the Ph.D. and a demonstrable record of excellence in research and professional leadership in the geological sciences.

The Geology Department currently has 19 full-time faculty members and grants degrees at the Bachelor's, Master's and Doctoral levels. The Head is responsible for maintaining a high standard of quality in both teaching and research within the Department.

Appointment will normally be made at the rank of Full Professor; salary is open. For equal consideration, applications should be received by March 1, 1978. The desired starting date is August 21, 1978. The University of Illinois is an equal opportunity/affirmative action employer. Interested persons should submit a letter of application, vitae and names of references to the Chairperson of the Search Committee:

Professor Charles Wert
Head, Department of Metallurgy
and Mining Eng.
201 Metallurgy and
Mining Building
University of Illinois at
Urbana-Champaign
Urbana, Illinois 61801

NIGERIAN INSTITUTE FOR OCEANOGRAPHY AND MARINE RESEARCH, VICTORIA ISLAND, LAGOS VACANCY

POST:—Principal, Marine Fisheries School.

QUALIFICATION:— A good honours degree in Zoology, a post graduate Diploma in Fisheries Management and at least 5 years appropriate field experience.

Salary Grade level 12 to N7,104 by 216 to N7,752.

METHOD OF APPLICATION

Detailed application stating clearly Full Names and Address, Age, Marital Status, Educational and Professional Qualifications obtained with dates, and names of Institutions attended, experience (with positions held, names of Organisations served and Dates), present post and salary, and names and addresses of three personal referees (not relatives), should be forwarded as soon as possible to:—

The Director,
Nigerian Institute for Oceanography
and Marine Research,
P.M.B. 127729,
Victoria Island,
Lagos. 1182(A)

INSTITUTE OF CANCER RESEARCH POSTDOCTORAL SCIENTIST— CYTOGENETICS

required to work at I.C.R., Sutton, Surrey, on a 3 year project designed to evaluate the long-term cytogenetic effects of chemotherapeutic agents on patients with malignant and non-malignant diseases. Previous experience in human cytogenetics essential.

Salary in scale £3,784 to £5,219 p.a. plus London Allowance £450 p.a.

Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 300/G/122. 1130(A)

UNIVERSITY OF
NOTTINGHAM
MEDICAL SCHOOL
PHARMACOLOGY

Applications are invited from those qualified in medicine, pharmacology or cognate disciplines for a LECTURESHIP tenable in the Department of Physiology and Pharmacology (Professor A. T. Birmingham—Professor of Pharmacology).

Pharmacology is taught as one of the basic medical sciences as part of an integrated curriculum for Part I of the Bachelor of Medical Sciences degree. An honours option in Physiology and Pharmacology is available to medical students for Part II of the degree.

There are excellent facilities for research in human and other branches of physiology and pharmacology, including an opportunity to participate in established research programmes. For this appointment an interest in biochemical and pharmacokinetic aspects of pharmacology would be an advantage.

Salary will be within the non-clinical scale for lectures (£3,333 to £6,655 under review) with membership of U.S.S./F.S.S.U. The successful applicant will be expected to take up the appointment as soon as possible.

Further details and application form from the Senior Assistant Registrar, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, to whom completed applications should be returned by February 20, 1978.

THE UNIVERSITY OF
MANCHESTER INSTITUTE
OF SCIENCE AND
TECHNOLOGY

DEPARTMENT OF BUILDING
Research on Energy
Consumption in Buildings

Applications are invited for a Special Research Assistant to work on simulation of building thermal performance and prediction of annual energy consumptions. The work will include the further development, construction and operation of analogue/digital simulation equipment. The successful candidate, male or female, should be familiar either with the thermal behaviour of buildings or with electronic engineering/digital techniques. The work is part of a research contract sponsored by the Building Research Establishment, Watford. Appointment will be for 2 years in the first instance.

The salary will be either £3,761 or £3,975 per annum (Range 1A).

Apply in writing, enclosing a full curriculum vitae including present salary and appointment, to the Registrar, U.M.I.S.T., P.O. Box 88, Manchester M60 1QD, by February 13, 1978. Quote reference B.U.I./10.

1153(A)

THE UNIVERSITY OF
MANCHESTER
ELECTRON MICROSCOPIST
AND MECHANICAL
ENGINEER

There are vacancies for two Research Associates in Geriatric Medicine—an Electron Microscopist (appointment for up to three years) and a Mechanical Engineer (appointment for up to two years). These appointments, preferably postdoctoral, are as part of a new team developing research into the aging bladder and the problems of incontinence. Salary range:—£3,333 to £5,015 p.a. The work will be carried out in the research laboratories of the Department of Geriatric Medicine at the University Hospital of South Manchester, Nell Lane, Manchester M20 8LR, under the overall direction of Professor J. C. Brocklehurst, from whom further details may be obtained.

1196(A)

UNIVERSITY OF SYDNEY
LECTURESHIP IN
VETERINARY CLINICAL
STUDIES

Appointee must have a degree in Veterinary Science acceptable for registration by the Board of Veterinary Surgeons of New South Wales and should have postgraduate experience in horse surgery. Postgraduate qualifications, teaching and research experience an advantage. Appointee will be located primarily in Sydney and be responsible for the conduct of the horse practice in the University Veterinary Hospital and Clinic and will participate in teaching of general and horse surgery.

The position is permanent but may be filled for three years in the first instance with the possibility of permanency during that time, or in certain cases return fares.

Salary Range: \$A14,851 to \$19,551 per annum.

Applications including curriculum vitae, list of publications and names of three referees by February 28, 1978, to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

1199(A)

VERTEBRATE
PALEONTOLOGIST
POSITION

THE UNIVERSITY OF KANSAS has a tenure track joint faculty-curator position for a Vertebrate Paleontologist. The appointment will be 9 months, 1/2-time in the Division of Systematics and Ecology and 12 months, 1/2-time in the Museum of Natural History, at the levels of Assistant Professor and Assistant Curator, respectively. Duties are teaching (undergraduate biology, lower vertebrate paleontology and anatomy courses), curation (in the paleontological collections) and development of an active graduate research program dealing with fossil amphibians and/or reptiles.

Applicant must have Ph.D. by the time duties are assumed or shortly thereafter and be qualified to curate a collection of fossil lower vertebrates. Applicants should send curriculum vitae, a statement of personal goals, and three letters of reference by March 15, 1978, to:

Dr Larry D. Martin
Museum of Natural History
University of Kansas
Lawrence, Kansas 66045

AN EQUAL OPPORTUNITY/
AFFIRMATIVE ACTION
EMPLOYER

THE FOOD AND AGRICULTURE
ORGANISATION OF THE
UNITED NATIONS

is looking for a

SENIOR TECHNICAL
ADVISOR

FOR A FISHERY, FISH CULTURE AND
AQUACULTURE PROJECT
IN IVORY COAST

The duration of the assignment is three years.

Duties: To direct the activities of a group of experts working on the implementation of a project whose purpose is:

- the creation of a training centre for extension workers;
- the development of river and lake fishery and of fish culture in the East and West Bandama zones;
- pre-promotion of fish culture by the establishment of pilot farms;
- the preparation of studies on the development of fish culture;
- the development of lake and lagoon aquaculture;
- the development of fish culture in rural areas.

Qualifications:

University degree in fishery, fish culture, agronomy, animal husbandry, forestry or any other field of science related to fishery development.

Experience:

Seven to 10 years practical experience in river and lake fishery and/or fish culture.

Languages:

Excellent knowledge of French and good working knowledge of English or Spanish.

Emoluments:

US\$20,000 to 30,000 net (not taxable), plus benefits and cost of living allowances.

Applications, accompanied by detailed curriculum vitae bearing the reference FID 306, should be sent soonest to:

Personnel Officer
Fisheries Department
Food and Agriculture Organisation of the
United Nations
Via delle Terme di Caracalla
00100 Rome
Italy

1139(A)

BUREAU OF HYGIENE AND TROPICAL DISEASES LONDON

I. DIRECTOR

Applications are invited for the post of Director of the Bureau,* which will fall vacant in December 1978. The appointment of the Director-designate will be made in September 1978.

The Bureau's functions are the collection, abstraction and distribution of information from literature published throughout the world on public health, tropical and other diseases, microbiology, food and nutrition etc and, in particular, the production of the monthly publications *Tropical Diseases Bulletin* and *Abstracts on Hygiene*.

The duties of the Director involve responsibility for the efficient management of the Bureau, liaison with Government departments and appropriate organisations to publicize the journals with a view to increasing their circulation world-wide, and the carrying out of the function of chief editor of both publications. Applicants should have medical qualifications registrable in the United Kingdom. Other desirable qualifications could include editorial experience in the medical field, a general knowledge of tropical medicine, medical parasitology and microbiology, an interest in community medicine and epidemiology, and a working knowledge of one or more European languages. Experience and suitability are more important than age, but applicants should preferably be not more than 50 years old.

The salary will be £11,400 and the selected applicant will be required to enter the contributory Universities Superannuation Scheme.

II. ASSISTANT DIRECTOR

Applications are invited for the post of Assistant Director of the Bureau, for which a vacancy may also arise in late 1978.

The duties of the Assistant Director are mainly of an editorial nature. The work could be combined with holding an honorary teaching appointment at the London School of Hygiene and Tropical Medicine which might be offered to a suitable candidate.

Applicants should preferably have medical qualifications registrable in the United Kingdom, but others with qualifications which are comparable to those specified for the Director (see above) are invited to apply. Applicants should preferably be not more than 50 years old.

The commencing salary will be in the range of £8,500 to £10,000 commensurate with the qualifications and experience of the selected applicant, who will be required to enter the contributory Universities Superannuation Scheme.

Applications, accompanied by personal details and the names of two referees, should reach Miss J. M. Dimond, Secretary, BHTD Managing Committee, Eland House, Stag Place, London, SW1E 5DH, not later than 28 February 1978.

*Applicants for the post of Director should state whether they wish to be considered also for the Assistant Director vacancy.

1202(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

Physiologists with a Ph.D. and/or M.D. and postdoctoral training are invited to apply for a faculty position in Physiology, in the Faculty of Medicine, Memorial University of Newfoundland. The position is envisaged to be at the Associate level, although the rank is open to negotiation. The duties include contributing to the teaching of physiology in an integrated medical curriculum as well as some physiology teaching to nursing and science students. The successful candidate should preferably have experience in teaching human and whole animal orientated mammalian physiology and would be expected to have or develop a research program. A strong background in cardiovascular/respiratory and/or renal/body fluids physiology would fit in well with our program. The Faculty of Medicine has recently expanded its facilities into a new Health Science Center which is a part of the Memorial University Campus and will shortly also include the St John's General Hospital. The salary will be commensurate with experience and qualifications and the position is available immediately or by negotiation. Applications, including curriculum vitae and the names and addresses of three references, should be sent to: Dr C. R. Trigg, Chairman, Physiology Search Committee, Faculty of Medicine, Memorial University, St John's, Newfoundland, Canada A1C 5S1. The application deadline is April 15, 1978. 1145(A)

LINCOLN COLLEGE (University College of Agriculture) New Zealand LECTURER IN BIOCHEMISTRY

The Council of Lincoln College invites applications for the position of Lecturer in Biochemistry.

Applicants should have a degree in Science or Agricultural Science, and a postgraduate qualification. Preference will be given to those with experience in Agricultural Biochemistry. Duties will include teaching Biochemistry in the course for Bachelor of Agricultural Science, and the appointee will be expected to carry out research in Biochemistry related to Agriculture.

Commencing salary according to qualifications and experience within the range NZ\$10,239 to \$12,543 per annum. At present salaries are supplemented by an "Interim Special Allowance" of 3.5 per cent.

Travel and removal expenses reimbursed up to specified limits. New Zealand Government Superannuation available.

Conditions of Appointment are obtainable from the Association of Commonwealth Universities, (Appts), 36, Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on March 6, 1978. 1136(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF FOOD SCIENCE Opportunities for Postgraduate Research

Applications are invited from good Honours graduates (or those expecting to obtain a good Honours degree within the next academic year) in: Biochemistry; Biological Sciences; Chemistry; Chemical Engineering; Chemical Physics; Mathematics, Physics, or appropriate allied subjects. Applicants should have a desire to apply chemical, biochemical and physical concepts to the solution of problems in food science.

Current departmental interest involves aspects of the chemistry and biochemistry of natural products, the physics of food materials, food microscopy and engineering problems involving food materials.

Enquiries should be addressed to Professor David S. Robinson, Procter Department of Food Science, The University, Leeds LS2 9JT. 1152(A)

WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales) TENOVUS LABORATORIES VELINDRE HOSPITAL WHITCHURCH, CARDIFF RESEARCH OFFICER (BIOCHEMIST)

Applications are invited from suitably qualified persons, preferably post-doctoral, for the post of Research Officer. The appointed person will be involved in the preparation and characterisation of tumour extracts for use in immunological tests concerned with the detection and monitoring of malignant disease. Experience in protein separation desirable. Salary within the range £3,333 to £3,971 (under review); starting point according to qualifications and experience. Application forms (quoting ref. No. 0) may be obtained from the Registrar, Welsh National School of Medicine, Heath Park, Cardiff. Further details obtainable from Dr J. A. V. Pritchard, Velindre Hospital, telephone No. Cardiff 63325 ext. 40. 1165(A)

MUSEUM DIRECTOR THE UNIVERSITY OF TEXAS

at Austin is seeking applicants for the position of Director of the Texas Memorial Museum. The Texas Memorial Museum is a multi-discipline natural history museum. The successful applicant must be qualified in an appropriate academic department.

Salary is commensurate with experience and qualifications of the successful applicant.

Applicants should submit a curriculum vitae, names of 5 references, appropriate statement of interests, and suitable reprints to: Chairman, Museum Search Committee, Burdine Hall 336, The University of Texas at Austin, Austin, Texas 78712.

Application deadline: April 1, 1978. An Equal Opportunity/Affirmative Action Employer. 1220(A)

HELLENIC ANTICANCER INSTITUTE

The Hellenic Anticancer Institute invites applications for a director of the Department of Medical Oncology in the St Savvas Hospital.

The applicants must have proven experience in Medical Oncology and administrative abilities.

Send applications to:
Hellenic Anticancer Institute
171 Alexandras Ave.
Athens, 603

to arrive before March 31, 1978. 1174(A)

M.R.C. CLINICAL RESEARCH CENTRE

(Northwick Park Hospital)

Watford Road, Harrow

Middlesex HA1 3UJ

There is a vacancy for a biochemist with experience in carbohydrate chemistry to join an immunochemistry research team working on structures of the carbohydrate antigens of normal and malignant cells. The programme will involve the purification and the immunochemical and structural analysis of oligosaccharides obtained from glycoprotein antigens. It will offer training in quantitative immunochemistry, and provide special opportunities for research on improved methods of oligosaccharide purification by high pressure liquid chromatography.

The successful applicant, who should be a graduate in science (with Ph.D./D.Phil., or with M.Sc. plus at least 3 additional years' postgraduate experience) will be required to apply for a Medical Research Council training fellowship through the normal annual competition for these awards. The award is tenable for up to 3 years, the closing date for applications is February 10, 1978, and interested persons should send a curriculum vitae to Dr Tenfeizi, from whom further information is available. 1164(A)

UNIVERSITY OF DURHAM LECTURER IN APPLIED PHYSICS

Applications are invited for a Lectureship in the Department of Applied Physics and Electronics tenable from October 1, 1978. Preference will be given to applicants with research interests in applied solid state physics.

Salary will be on the scale £3,333 to £6,655 per annum (under review) plus superannuation.

Applications (3 copies) naming 3 referees should be sent, by February 17, 1978 to the Registrar and Secretary, Science Laboratories, South Road Durham DH1 3LE. 1159(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR RESEARCH ASSISTANT

Salary £2,904 to £3,333 p.a.

Applications are invited for a post of Research Assistant to work in the Xylem Physiology Laboratory of the Department of Forestry and Wood Science, on the control of wood structure within hardwood trees. The project is mainly concerned with environmental effects on the developmental anatomy of wood grown in growth cabinets and in the field. The post is supported by NERC, and is for three years starting April 1, 1978. Applicants should possess a good honours degree in Forestry, Botany, or a closely related subject.

Applications (three copies), giving details of age, qualifications and experience, together with the names and addresses of two referees, should be sent by February 13, 1978, to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 3DG, from whom further particulars may be obtained. 1195(A)

**UNIVERSITY OF
DUNDEE
DEPARTMENT OF
BIOCHEMISTRY
POSTDOCTORAL
BIOCHEMIST**

Biochemists are invited to apply for a Postdoctoral Fellowship to work in collaboration with Dr Brian Burchell on a project grant supported by the Medical Research Council. The aim of the project is to examine the molecular mechanisms involved in the regulation of hepatic microsomal UDP-glucuronyltransferase activity. Applicants should have experience in enzymology and/or lipid chemistry and a knowledge of membrane-bound enzymes.

The appointment will be initially for one year and renewable for a further two years. The position can start immediately, but candidates wishing to begin at any time up to June 1, 1978 will be considered. Starting salary in range 1A of the University Research Staff scales (£3,333 to £3,761, according to age and experience).

Applications, containing a curriculum vitae and the names of two referees, should be sent as soon as possible to The Secretary, The University, Dundee DD1 4HN. Please quote Reference EST/16/78J. 1161(A)

**MEMORIAL UNIVERSITY
OF NEWFOUNDLAND
DEPARTMENT OF GEOLOGY**

The Department of Geology invites applications for three faculty positions in **Sedimentology and Marine Geology** with special reference to the Labrador continental margin (subject to the availability of funds).

One appointment will be a regular faculty position at a salary and rank commensurate with qualifications and experience. The appointee will direct and participate in the activities of a research group working in the following specialities: Mesozoic and Cenozoic clastic sedimentology, clay mineralogy, sedimentary geochemistry and micropaleontology. Applications from suitably qualified candidates with working experience in the petroleum industry will be especially welcome.

Two appointments will be at the rank of Assistant Professor (Research) and will be for a two-year term in the first instance. Applicants should have proven research ability in one (or more) of the specialist fields listed above.

Applications for all three positions, which must include a detailed curriculum vitae and the names and addresses of three referees, should be sent by 14-ch 31, 1978 to: Dr David Skevington, Head, Department of Geology, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X5. 1170(A)

**UNIVERSITY OF
SOUTHAMPTON
TENOVUS RESEARCH
LABORATORY**

A postdoctoral immunologist or biochemist with some immunological training is required to join a team engaged principally on cell surface studies of leukaemic lymphocytes. Appointment for three years in the first instance. Salary on University Research Fellow Scale 1A, £3,333 to £5,627 p.a. (under review). Enquiries to Professor G. T. Stevenson, Tenovus Research Laboratory, General Hospital, Tremona Road, Southampton SO9 4XY.

Applications to Mr C. W. L. Swann, The University, Southampton SO9 5NH quoting reference 877/RN. 1132(A)

**GREATER GLASGOW
HEALTH BOARD—
WESTERN DISTRICT**

**GRADUATE
SCIENTIST**

**UNIVERSITY DEPARTMENT
OF BACTERIOLOGY
AND IMMUNOLOGY
Western Infirmary, Glasgow**

Applications are invited for the post of Graduate Scientist in the N.H.S., concerned with development and research in Immunology. The appointee is expected to possess a first or upper second class Honours degree in a biological science, preferably microbiology, immunology or biochemistry.

The appointee is expected to participate in research investigations in immunology under the direction of Professor R. G. White. The appointment would be expected to lead to a career in immunology or microbiology within the National Health Service and progress would be encouraged through the examinations of the Royal College of Pathologists in these subjects. Alternatively the appointment could form the basis for investigative work leading to a higher University degree.

Candidates with a Ph.D. and experience in immunology or microbiology could also apply.

Salary will be according to degree and experience since graduation. Applications to: Miss B. S. Young, Sector Administrator, Western Infirmary. 1127(A)

**UNIVERSITY OF READING
DEPARTMENT OF PHYSIOLOGY
AND BIOCHEMISTRY
RESEARCH ASSISTANT**

required as soon as possible for a three-year research project funded by S.R.C. on the neuroendocrine control of ovulation in birds. Applicants should be graduates in physiology, pharmacology or zoology and should have a good background in neurophysiology. An interest in neuroendocrinology would be an advantage.

Starting salary £2,904 p.a. (under review). U.S.S. superannuated.

Apply, quoting Ref. MN. 05A, with the names of two referees to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. 1204(A)

**UNIVERSITY OF GLASGOW
RESEARCH TECHNICIAN**

Applications are invited for the post of Research Technician in the Department of Pathological Biochemistry, Royal Infirmary, Glasgow (Professor H. G. Morgan). The successful candidate, who must have extensive laboratory experience, will assist in the study of the effects of various physiological or pharmacological stimuli on the metabolism of human high density lipoproteins. The post is for one year in the first instance, within the scale of £2,688 to £2,760 p.a. Applications to Dr J. Shepherd, Department of Pathological Biochemistry, Royal Infirmary, Glasgow G4 0SF (041-552-3535, Ext. 5267) within three weeks of appearance of the advertisement. In reply please quote Ref. No. 4047M. 1192(A)

**ZOOLOGISTS
Ecology and Control
of Rodent Pests**

Posts are available in two departments concerned with the control of rodent pests. Each involves field studies of their ecology and behaviour, the development of control methods and the assessment of rodenticide performance. The scientists appointed will also provide training in survey and control methods.

Ministry of Agriculture, Fisheries and Food

Ref: SB/35/AF

The work will include the collection of data to measure the extent of the rodent problem. The post is based at Tolworth with field studies in Powys. Appointment as Higher Scientific Officer.

Ministry of Overseas Development

Ref: SB/1/JA

The appointment will be at Tolworth and the successful candidate will be expected to spend up to 80% of the time overseas. Appointment as Higher Scientific Officer or Senior Scientific Officer.

For both posts candidates must have a good honours degree or equivalent in Zoology/Ecology/Applied Biology and have at least 2 years postgraduate experience, preferably in ecology on control of small wild mammals.

Candidates for appointment as Senior Scientific Officer (£4980—£6575) should normally be aged under 32, for Higher Scientific Officer (£4030—£5250) normally under 30. Starting salary will depend on qualifications and experience.

For further details and application form (to be returned by 17 February 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote appropriate reference. 1129(A)

VICTORIAN COLLEGE OF PHARMACY LTD.

Melbourne Australia

Position of Dean (Principal) of the College

\$30,786 (Australian)

The Council of the College invites applications for the position of Dean of the College from January 1, 1979, when Dean Nigel C. Manning, C.B.E., retires.

The position is that of the chief executive of the College, and the successful applicant will have enjoyed a broad scientific academic background, preferably in the pharmaceutical sciences, and will have extensive academic and administrative experience.

The occupant will receive a professorial salary and an additional allowance of \$4,000 per annum.

Further information on the position may be obtained from the Registrar of the College, with whom applications and the names of three referees should be lodged at 381 Royal Parade, Parkville, Victoria, Australia 3052. The closing date for receipt of applications is April 14, 1978.

Council reserves the right to appoint by invitation.

1146(A)

Wellcome

Senior Technicians

Pharmacology

Opportunities exist in our expanding Pharmacology Department for two senior technicians. The work will be in the general area of biochemical pharmacology and a wide experience in this field will be essential in order to contribute to a variety of projects.

Applicants, who may be male or female, should have an HNC or degree level qualification in an appropriate discipline.

Our Laboratories are situated in pleasant parkland surroundings, within easy reach of Bromley and Beckenham, about 12 miles from Charing Cross. Conditions of employment are attractive and include four weeks' holiday, company pension fund, sick pay scheme, subsidised canteen and generous assistance with relocation expenses where appropriate.

Please apply in writing to
N. J. Michell,
Personnel Officer,
The Wellcome Research Laboratories,
Langley Court, Beckenham,
Kent BR3 3BS,
quoting ref U/841.

1181(A)

THE ROYAL VETERINARY COLLEGE University of London Division of Preclinical Studies DEPARTMENT OF ANATOMY

Applications are invited for the post of
LECTURER IN ANATOMY

The post becomes vacant on September 1, 1978, and is based at Camden Town. The person appointed will be expected to undertake teaching of the anatomy of large animals and will be expected to engage in research.

SALARY SCALE (under review): £3,805 to £7,105 including London Allowance. Initial salary determined by qualifications and experience. Superannuation under the Universities' scheme. Removal expenses up to £650 may be reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone: 01-387 2898.

CLOSING DATE FOR APPLICATIONS: February 24, 1978. 1125(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF ANIMAL PHYSIOLOGY AND NUTRITION

Applications are invited for the post of **LECTURER** in the above Department. Applicants must have adequate lecturing experience and should have research interests in the endocrinological aspects of reproduction of farm livestock.

Salary on the lecturer scale £3,333 to £6,655.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 61/2/D. Closing date for applications February 20, 1978.

1151(A)

MASSEY UNIVERSITY Palmerston North, New Zealand **LECTURER IN PLANT PATHOLOGY**

Applications are invited for the above-mentioned position within the Department of Horticulture and Plant Health.

Main responsibilities will be teaching of plant pathology to degree and diploma courses within the Faculty of Agricultural and Horticultural Sciences.

Preference will be given to applicants with doctorate qualifications, some teaching experience, and with proven research interests in one or more of the following fields:— plant virology, plant bacteriology, plant nematology, plant pathogenic fungi.

Commencing salary, according to qualifications and experience, within the range NZ\$10,585 to NZ\$12,969.

Further details of the position and of the University, together with Conditions of Appointment and information to be supplied by applicants, may be obtained from the Association of Commonwealth Universities (Acpus), 36 Gordon Square, London W1P 0PF, or from the Registrar of the University.

Applications close on **February 28, 1978. 1179(A)**

UNIVERSITY OF STRATHCLYDE

Applications are invited for a
LECTURESHP

in the **DEPARTMENT OF APPLIED MICROBIOLOGY**

from persons holding an honours degree and a higher degree, one of which should be in microbiology or a related subject. Candidates should have, preferably, experience in aspects of biotechnology although other interests such as design and use of fermenters, pollution, or biodegradation, will be considered. Relevant industrial experience in lieu of a higher degree would also be acceptable.

Salary scale £3,333 to £6,655 per annum (under review) with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 2/78) and enclosing a self-addressed envelope (9"x4"), may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW with whom applications should be lodged by February 11, 1978.

1167(A)

university of wales university college of swansea

Senior Research Assistant

Applications are invited for the vacancy of Senior Research Assistant in the Department of Zoology to work with Dr. N. A. Ratcliffe on an N.E.R.C. sponsored project on invertebrate host defence mechanisms and the influence of environmental parameters on these reactions. Candidates should be near to completing or have completed a Ph.D. in Marine Microbiology, Cell Biology or Immunology and should have experience in the use of radioisotopes and basic microbiological techniques. A knowledge of cell separation and fractionation, ecology and/or histochemistry would also be advantageous.

The appointment, which will date from March 1, 1978, or as soon as possible thereafter, will be for one year in the first instance, with the possibility of renewal for a further two years. The commencing salary will be on a scale up to £3,761 per annum plus U.S.S./U.S.D.P.S. benefits.

Further particulars and application forms (2 copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by **Friday, February 10, 1978. 1124(A)**

RU leiden

UNIVERSITY OF LEIDEN THE NETHERLANDS

FACULTY OF SCIENCE

The DEPARTMENT OF CHEMISTRY invites applications for the tenured position of

Full Professor in Inorganic Chemistry

Applicants should have a broad knowledge and experience in the field of inorganic chemistry. Responsibilities will include teaching. The appointee is expected to coordinate the activities of the inorganic chemistry section.

Applications with curriculum vitae, a list of publications, full details of qualifications and experience (including teaching), references etc. should be addressed within 30 days of this publication to the Secretary of the Department of Chemistry, dr. A. B. Ruigrok, Gorlaeus Laboratories, P.O. Box 9502, Leiden, The Netherlands, mentioning vacancy number 8-010/2407.

1138(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of

POSTDOCTORAL

RESEARCH ASSISTANT

in the DEPARTMENT OF BIO-CHEMISTRY to study the nature of the biosynthetic precursors of collagen and elastin. The appointment, which is funded by a grant from the S.R.C. to Dr R. Harwood, is tenable for 3 years and is available as soon as possible. The project will involve the analysis of cell-free translation products and previous experience of nucleic acid biochemistry or protein biosynthesis would be advantageous, though not essential. Salary within Research and Analogous Range IA: £3,761 to £4,190.

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained. Closing date **February 27, 1978. Please quote reference 1403. 1187(A)**

**UNIVERSITY OF SYDNEY
LECTURESHIP IN ANIMAL
HUSBANDRY
DEPARTMENT OF
ANIMAL HUSBANDRY**

This position is in the Poultry Husbandry Research Foundation Unit at Camden, New South Wales. Applicants should have extensive postgraduate experience in non-ruminant nutrition, with particular reference to poultry. Practical experience with the poultry and/or pig industries an advantage. He/she will be required to participate in general teaching activities of the Department as well as in his/her own area of special expertise, and to be involved in research and supervision of postgraduate students.

Position is permanent but may be filled for three years in the first instance with the possibility of permanency during that time, or in certain cases return fares.

Salary range: \$A14,851 to \$19,551 per annum.

Applications including curriculum vitae, list of publications and names of three referees by February 28, 1978, to Registrar, University of Sydney, NSW 2006, Australia. Information available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 1134(A)

**THE UNIVERSITY OF
LIVERPOOL**

Department of Applied Mathematics and Theoretical Physics

Applications are invited for a post of Senior Research Assistant in the Department of Applied Mathematics and Theoretical Physics. The project is financed, by the N.E.R.C., for a period of three years from October 1, 1978. The person appointed will work with Dr P. C. Chatwin on a project entitled "The use of numerical simulation techniques in the analysis of data on the diffusion of chemical and biological species in estuaries." Candidates should have research experience in fluid mechanics (in any appropriate discipline including Applied Mathematics, Oceanography or Engineering), and be prepared to make extensive use of a computer. The post is suitable for persons who expect to have a Ph.D. by the starting date.

The initial salary will be £3,333 per annum on a scale rising to £4, per annum.

Applications, together with the names of two referees, should be received not later than March 6, 1978 by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/653/N. 1140(A)

Senior Research Pharmacologist

A vacancy has arisen at our Welwyn Garden City site for a Senior Research Pharmacologist in the Pharmacology Department.

The Department comprises three sections, cardiovascular, anti-inflammatory and general pharmacology. The successful applicant, male or female, will be required to lead a small project team and contribute to the overall Research effort in the general pharmacology section.

Applications are invited from those with 2 to 3 years' post-doctoral experience who can demonstrate achievements in innovative research.

We offer excellent working conditions in modern and well-equipped laboratories. The salary will be commensurate with experience, additional benefits and facilities include a Christmas Award, contributory pension scheme, free BUPA membership, a subsidised restaurant and, in appropriate cases, assistance towards relocation expenses.

For further information and an application form, please contact the Research Personnel Department (quoting reference RD4) Roche Products Limited, PO Box No 8, Welwyn Garden City, Hertfordshire AL7 3AY, telephone Welwyn Garden 28128. The closing date for applications is 23 February 1978.

1158(A)

ROCHE

**M.R.C. CLINICAL RESEARCH CENTRE
(Northwick Park Hospital)**

Watford Road, Harrow,
Middx. HA1 3UJ

The division of surgical sciences has a vacancy for a postdoctorate to work on immunity to trypanosoma cruzi. This position which is tenable for one year only is suitable for an immunologist, microbiologist, parasitologist or biochemist.

Salary within the range £3,995 to £5,219 p.a. plus £450 p.a. London allowance.

Please contact Dr C. Sanderson on 01-864 5311 ext. 2412 for further details and Joan Tucker-Bull ext. 2685 for application form quoting ref. 128/1/4332. Closing date February 24.

1128(A)

**UNIVERSITY OF
EAST ANGLIA
NORWICH
DIRECTOR OF THE
CLIMATIC RESEARCH
UNIT**

Applications are invited from persons with suitable qualifications and experience for the post of Director of the Climatic Research Unit, which is associated with the School of Environmental Sciences. This position will become vacant on the retirement of the present and founding Director of the Unit, Professor H. H. Lamb. The appointment will be at Professorial or Readership level, according to the age and experience of the successful candidate, and will be tenable from October 1, 1978, or as soon as possible thereafter. Salary will be on the Professorial scale £8,106 to £9,587 or on the Reader scale £6,443 to £7,951 (under review).

Applications (one copy only) giving the names of three persons to whom reference may be made, should be lodged with the Establishment Officer, University of East Anglia, Norwich NR4 7TJ (telephone 0603 56161 ext. 2126) from whom further particulars may be obtained, not later than February 28, 1978. No forms of application are issued. In naming three referees you are particularly requested to give only the names of those who can immediately be approached. 1184(A)

**THE UNIVERSITY OF
LEEDS
DEPARTMENT OF
GENETICS**

Applications are invited for the following posts in the above department:—

1. LECTURESHIP

Applicants from all fields of genetics will be welcome. The post is available from October 1, 1978. Salary on the lecturer scale £3,333 to £6,655 (under review). Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 50/3/D. Closing date for applications February 16, 1978.

**2. RESEARCH
FELLOWSHIP**

Postdoctoral Research Fellow required for a period up to three years from July 1, 1978, to work in the above department on the biosynthesis and mode of action of cytokinins in the moss *Physcomitrella patens*. Applicants with research experience in either plant physiology or microbial genetics would be especially suitable. Salary on the IA Scale for Research and Analogous Staff: £3,333 to £5,627 (under review). Applications, together with the names of two referees, should be returned to Professor D. J. Cove, Department of Genetics, University of Leeds, Leeds LS2 9JT (from whom further particulars may be obtained), not later than March 14, 1978. 1193(A)

**UNIVERSITY OF
NOTTINGHAM**

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of Post Doctoral Research Associate or Postgraduate Research Assistant. The work involves a study of protein reabsorption in the kidney of a lower vertebrate. Candidates should preferably have an interest in electron microscopy, renal physiology and micro-puncture techniques but previous experience is not essential.

Salary £3,333 per annum.

Application forms returnable not later than February 13, 1978 from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. 1197(A)

**UNIVERSITY OF
CAMBRIDGE
DEPARTMENT OF
APPLIED BIOLOGY**

A vacancy exists for a Plant Breeder to continue an existing programme on the development of a high yielding, disease resistant variety of navy bean, *Phaseolus vulgaris*, adapted to the S.E. of England. The project is supported by outside funds for 3 years. Salary in the range £3,119 to £3,975 according to age and qualifications. Further information from and applications to the Secretary, University of Cambridge, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX by February 9, 1978. 1163(A)

**THE NATIONAL INSTITUTE
FOR HIGHER EDUCATION, LIMERICK
APPLIED MATHEMATICS LECTURER**

The person appointed will have expertise in the application of mathematics to problems in engineering, the physical sciences or business. While an appropriate honours degree is the minimum academic qualification it is likely that the successful applicant will hold a postgraduate qualification. The appointee will contribute to existing courses and to the development of new courses.

SALARY: £5,850 to £7,455 plus £100 p.a. marriage and £70 p.a. child allowances together with other benefits.

Application material available from the Personnel Office, The National Institute for Higher Education, Limerick, to be completed and returned by Friday, February 17, 1978. 1210(A)

FOOD AND AGRICULTURE
ORGANISATION OF THE
UNITED NATIONS

requires a

SENIOR AGRICULTURE ADVISER

for the Latin American Regional Centre for Aquaculture being established in Pirassununga, State of São Paulo, Brazil.

The incumbent will be responsible for the organisation of research teams for implementing systems oriented research on selected production systems and will co-ordinate the overall research and training activities of the centre.

The incumbent should possess:

University degree in biology, zoology, fisheries science or other related disciplines, preferably to the level of Doctor of Philosophy.

At least 10 years' experience in planning and execution of aquaculture research preferably in developing countries.

Applications with detailed Curriculum Vitae, quoting the reference FID 309 should arrive at the following address not later than March 31, 1978.

Personnel Officer
Fisheries Department
Food and Agriculture Organisation
Via delle Terme di Caracalla
00100 Rome, Italy 1190(A)

UNIVERSITY OF SINGAPORE CHEMICAL ENGINEERING

Applications are invited for teaching appointments in the Department of Chemical Engineering. Candidates should possess postgraduate qualifications and have relevant teaching/research/industrial experience. Preference will be given to those who are able to teach in one or more of the following areas: PROCESS CONTROL; THERMODYNAMICS; PLANT DESIGN; FOOD TECHNOLOGY; PETROCHEMICAL PROCESSING. Gross monthly emoluments in the range from S\$1,420 to S\$5,045 approx., the initial amount depending on the candidate's qualifications and experience and the level of appointment offered. In addition, the University pays a 13th month annual allowance of one month's salary in December of each year. Leave, medical, housing and provident fund benefits are also available. Candidates should write to:

The Registrar, University of Singapore, Singapore 10, giving curriculum vitae (bio-data), with full personal particulars and also the names and addresses of three referees. 1175(A)

OXFORD POLYTECHNIC

Technician — Geology

(£2,983 to £3,323 including all supplements)

A technician is required in the Geology section of the Department of Construction. Duties will include special responsibility for cutting thin sections.

Further particulars and application forms may be obtained from The Administrator, Oxford Polytechnic, Oxford OX3 0BP. 1149(A)

UNIVERSITIES OF GLASGOW AND STRATHCLYDE

Applications are invited for a
POSTDOCTORAL
RESEARCH ASSISTANT

in the DEPARTMENT OF PURE AND APPLIED CHEMISTRY funded by S.R.C. for studies of morphologically related ultrasonic relaxation phenomena in polymeric solids to be performed in collaboration with the Groups headed by Professor J. Lamb, Department of Electrical Engineering, University of Glasgow and Professor A. M. North, Department of Pure and Applied Chemistry, University of Strathclyde.

The appointment is for a period of two years.

Salary on the national scale for research and analogous staff Range 1A with a commencing salary within the range £3,333 to £3,761 per annum (under review). Superannuation benefit.

Applications (quoting R2/78) enclosing a curriculum vitae and the names of two referees, should be sent to Dr R. A. Pethrick, Department of Pure and Applied Chemistry, University of Strathclyde, Thomas Graham Building, Glasgow G1 1XL, as soon as possible. Further particulars are available from Dr Pethrick on request. 1186(A)

UNIVERSITY OF QUEENSLAND

Australia

DIRECTOR OF

HERON ISLAND

RESEARCH STATION

The appointee will be responsible for the operation of the Station which provides teaching and research facilities for visiting scientists and students. He or she will be expected to engage in a programme of research and should have experience in conducting research in a field of biology, geology or geography appropriate to a coral reef. A higher degree is desirable.

The appointment will be made to the staff of the University at the level of Reader or Senior Lecturer according to qualifications and experience and will be for a period of three years commencing April 1, 1979.

Salary: Senior Lecturer: \$A19,971 to \$A23,299; Reader: \$A26,365. Other Benefits: Superannuation, travelling and removal expenses. A rent-free house is supplied.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

Applications close on April 30, 1978. 1180(A)

ACADEMIC GASTROENTEROLOGY POSITIONS AVAILABLE

The State University of New York at Buffalo is establishing a new program in gastroenterology. Positions available at all academic levels; research is an important facet. Laboratory space and initial support funds are available. The program utilizes the clinical facilities of the E. J. Meyer Hospital, a new 750 bed hospital, the Buffalo General Hospital, the Children's Hospital, the Veteran's Administration Hospital and Roswell Park. The basic science department of the University and Roswell Park are available for consultation and collaboration.

Address inquiries and curriculum vitae to: Milton M. Weiser, M.D., Chief, Gastroenterology and Nutrition, SUNY at Buffalo, c/o GI Laboratory, Massachusetts General Hospital, Boston, MA. 02114.

Affirmative Action/Equal Opportunity Employer. 1219(A)

FELLOWSHIPS

UNIVERSITY OF LANCASTER

Department of
Physics

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a Postdoctoral Research Fellowship funded by the S.R.C. for studies of the breakdown of superfluidity in liquid helium-4 at millikelvin temperatures. The work will be carried out under the direction of Dr P. V. E. McClintock. Applicants should have had considerable experience of low temperature experimental techniques, particularly of measurements below 1 K and preferably including dilution refrigeration; some knowledge of computing would be an advantage.

The appointment, for two years, is on grade 1A with a starting salary in the range (subject to review) £3,333 to £3,975.

Further particulars may be obtained (quoting reference L16/D) from the Establishment Officer, University House, Lancaster LA1 4YW to whom applications (five copies) naming three referees should be sent not later than February 21, 1978. 1194(E)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

DEPARTMENT OF
BIOCHEMISTRY AND
SOIL SCIENCE

POSTDOCTORAL RESEARCH FELLOWSHIP PHYTOCHEMISTRY ECOLOGY

Applications are invited for a N.E.R.C. Postdoctoral Fellowship to work in collaboration with Dr R. G. Wyn Jones on the accumulation of organic solutes, particularly nitrogenous compounds in halophytic and xerophytic plants.

Experience in the isolation and characterisation of small molecular weight organic compounds and an interest in plant ecology and taxonomy will be highly desirable. The appointment is for two years and will commence on May 1, 1978, at a salary of £3,333 per annum plus superannuation.

Applications (two copies), together with the names and addresses of two referees should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, by February 25, 1978, from whom further details may also be obtained. 1088(E)

QUEEN MARY COLLEGE

University of London
PHYSICS DEPARTMENT

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP

in Theoretical High Energy Physics for programme on Gauge Field Theory and Quantum Gravity.

Initial salary in range (including London Allowance) £3,805 to £4,233 p.a. (under review).

Further details available from Dr J. M. Charap. Applications, including curriculum vitae, list of publications and names of 2 referees, to be sent to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS, as soon as possible. 1215(E)

RESEARCH FELLOWSHIP

A POSTDOCTORAL FELLOW required as soon as possible for an appointment of two years with possible extension to three years.

The work will be on the mechanisms by which viruses convert cells from a normal to malignant state, with emphasis on leukaemia-inducing viruses.

Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr J. Wyke (tel: 242 0200, ext. 267/270).

Applications with curriculum vitae and names of two referees, should be sent to:

The Secretary,
Imperial Cancer Research Fund,
Lincoln's Inn Fields,
London WC2A 3PX,

by March 17, 1978, quoting Ref. 61/78. 1209(E)

UNIVERSITY OF CAMBRIDGE BROADBANK FELLOWSHIPS

Applications invited for Fellowships for full time research normally at Cambridge in Biochemistry or Biophysics with special reference to the principles and practice of food preservation. Tenure normally from October 1, 1978, for one year first instance but may be extended for one or two further years. Candidature open, but preference to postdoctoral applicants.

Pensionable salary for postdoctoral Fellow in range £3,150 to £4,000 according to experience and qualifications. Compulsory superannuation.

Applicants should ascertain that there is a laboratory in Cambridge willing to accommodate them and must outline research proposed indicating bearing on principles and practice of food preservation and include full curriculum vitae, copies of papers published or references thereto and names and addresses of at least two referees.

Full details available from and applications (ten copies) to reach the Secretary to the Managers of the Broadbank Fund, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX, not later than March 1, 1978. 1205(E)

RESEARCH FELLOWSHIP IMPERIAL CANCER RESEARCH FUND LABORATORIES Mill Hill, NW7

A postdoctoral Fellow is required to join a group working on the genetic and biochemical analysis of certain heat activated loci in *Drosophila melanogaster*, using cloned DNA fragments to investigate their organisation and expression.

Appointment will be for two years in the first instance with possible extension for a third year. Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr D. Ish-Horowicz (01-959 3236).

Applications with curriculum vitae and names of two referees, should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, by February 28, 1978. 1208(E)

ONTARIO CANCER INSTITUTE POSTDOCTORAL FELLOWSHIP

available to join a group working on the genetics and molecular biology of murine oncornaviruses and erythropoiesis. Candidates should be about to graduate in virology, biochemistry or cell biology in the spring or summer of 1978. Applicants should send curriculum vitae with three letters of references to Drs T. W. Mak or A. Bernstein, Division of Biological Research, Ontario Cancer Institute, 500 Sherbourne St., Toronto, Ontario, Canada M4X 1K9. Stipend will be \$11,600 to \$12,700 annually. 1093(E)

STUDENTSHIPS

BRITISH MUSEUM (NATURAL HISTORY)

POSTGRADUATE RESEARCH STUDENTSHIPS 1978

Two studentships will be available, tenable for 3 years, at the British Museum (Natural History) and commencing October 1978.

Arrangements will be made with an appropriate university for higher degree registration and joint supervision of the research project.

The research areas for which applications are invited are as follows:-

DEPARTMENT OF BOTANY

1. Evolutionary relationships in the Celastraceae with special reference to *Maytenus*, a source of important anticancer drugs.

DEPARTMENT OF PALAEONTOLOGY

2. Ultrastructure of some fossil Rhodophyta (red algae), and their relationships.

Facilities are available for scanning and transmission electron microscopy, serology, biochemistry and biometrics. In addition, students will have access to the Museum's extensive library.

ELIGIBILITY

Applicants to be aged 27 or less, ordinarily resident in Great Britain, and to have a first or upper-second class honours degree; students graduating in 1978 can be offered awards subject to their degree results reaching this level.

Students interested in applying should write to The Secretary (Postgraduate Studentships), British Museum (Natural History), Cromwell Road, London SW7 5BD, for application forms and conditions of the awards.

Closing date for receipt of completed application forms—March 20, 1978. 1157(F)

THE ANIMAL VIRUS RESEARCH INSTITUTE Pirbright, Woking, Surrey A.R.C. RESEARCH STUDENTSHIPS 1978

Applications are invited from Science students graduating this year for an Agricultural Research Council Research Studentship tenable for up to 3 years at the Animal Virus Research Institute. The award is in the Biochemistry Department, where the successful candidate would be concerned with the characterisation of polypeptides of enteroviruses belonging to the Coxsackie B5 and swine vesicular disease groups. The project is aimed at establishing the regions in the nucleic acid coding for the particular differences in the functional coat proteins.

Details of the awards are available from the Secretary, Animal Virus Research Institute, Pirbright, Woking, Surrey, GU24 0NF. Applications should be received by March 31, 1978. 1217(F)

EXETER COLLEGE OXFORD

The College proposes to elect to an Usher Cunningham Studentship for graduate work in Oxford in any branch of Medical Science.

The Studentship will be tenable from October 1, 1978. The financial and other provisions are at the direction of the College but are likely to be similar to those governing awards made by a Research Council.

Applicants must be under twenty-five years of age and must be or become resident members of Exeter College. They must also be accepted as graduate students by a Faculty Board.

Application with the names of two referees should be made to the Rector by February 25, 1978. 1143(F)

COURSES

British Council Course ADVANCE ELECTRON MICROSCOPY FOR BIOLOGISTS

September 17-29, 1978

in
Norwich

The Director of Studies will be Professor R. Markham, F.R.S., Director of the John Innes Institute.

Recent advances in electron microscopy techniques are of considerable importance in the study of plant tissues, cells, organelles, viruses, macromolecules, nucleic acids and other biological materials. This course aims to provide its participants with experience in these techniques and in the experimental methods used in the preparation of biological specimens for high resolution electron microscopy, the operation of the microscopes and the analysis and interpretation of electron micrographs.

The course, which is residential, is designed for non-UK citizens who are practising electron microscopists who wish to extend their skills in high resolution electron microscopy of biological materials.

Information and forms for registration may be obtained from local Representatives of the British Council or from Courses Department, The British Council, 65 Davies Street, London W1Y 2AA.

Completed application forms must be received in London by May 1, 1978. Fee £475. 1171(D)

UNIVERSITY OF SALFORD DEPARTMENT OF BIOLOGY

Applications are invited for the one year course for the degree of M.Sc. in ENVIRONMENTAL RESOURCES.

Applicants should possess an honours degree in a Biological Science, Geography, or Geology. Graduates in Geography, or Geology will be required to have a sufficient knowledge of Biology to undertake the course.

Further details can be obtained on application to the Course Tutor, Department of Biology, University of Salford, Salford M5 4WT. 1150(D)

INSTITUTE OF PSYCHIATRY, NEUROLOGY AND OPHTHALMOLOGY (British Postgraduate Medical Federation, University of London) POSTGRADUATE COURSE IN NEUROCHEMISTRY

This is a ONE-YEAR Course leading to the degree of M.Sc. in Neurochemistry. It offers graduates in science and medicine training in basic and applied neurochemistry. The Course consists of lectures, seminars and laboratory work and, in the second and third terms, research on a neurochemical topic.

Applicants should have an honours degree in Biochemistry or a Biological subject with some Biochemical component, or be Medically qualified. The Course is recognised by the Medical Research Council as an Advanced Course for the award of Training Scholarships to suitably qualified applicants.

Application for the Academic year October 1978-July 1979 should be addressed to the Secretary, Course in Neurochemistry, Department of Biochemistry, Institute of Psychiatry, De Crespigny Park, Denmark Hill, LONDON SE5 8AF, England. 1200(D)

SYMPOSIUM

PERPIGNAN UNIVERSITY

"Contribution multidisciplinaire à la Systématique: Umbelliferae" 18-21 Mai 1977 (2nd International Symposium on the Umbelliferae) Perpignan, France.

50 Contributions (in English, French, German and Spanish) devoted to taxonomy, biology, evolution, ecology, biogeography, ethnobotany, pharmacology and to agricultural aspects of the Umbelliferae.

Size: 32 by 30, 832 p. plus Indexes, paper bound (offset printing), 200 F.F., A. M. CAUWET & J. CARBONNIER Ed., Perpignan University—66025—Cedex (France). 1201(M)

ASSISTANTSHIPS

THE UNIVERSITY OF BRITISH COLUMBIA DEPARTMENT OF CHEMISTRY GRADUATE TEACHING ASSISTANTSHIPS

Graduate Teaching Assistantships are available for candidates with high academic records who wish to pursue further studies towards the M.Sc., and Ph.D. degrees in chemistry. Excellent research facilities are available in all areas of modern chemical science, ranging from bio-inorganic chemistry to chemical physics. The minimum stipends including summer research assistantship will be \$6,120.00 per annum for first year and \$6,500.00 for students entering with a Master's Degree. The stipends are currently under review. In addition, many special merit awards are made to those Graduate Teaching Assistants who show excellence in the performance of their duties. Numerous graduate scholarships are also available for students with outstanding academic records.

Application forms and further particulars may be obtained from the undersigned:

UNIVERSITY OF CAMBRIDGE

Applications are invited from Chemists, Physicists or Geologists for a two-year

POSTDOCTORAL ASSISTANTSHIP

with a small group investigating light element (carbon and nitrogen) geochemistry of lunar samples and meteorites. Practical experience in computerised mass spectrometry and an ability to work with small samples is desirable. Some previous involvement in stable isotope analysis could be advantageous since the group is currently developing techniques in this field which could have considerable application in a number of important research areas.

The salary range is £3,333 to £3,547. Further details from, or curriculum vitae and the names of two referees to, Dr C. T. Pillinger, Department of Mineralogy and Petrology, University of Cambridge, Downing Place, Cambridge CB2 3EW. Telephone No. 0223-64131, ext. 283. 1221(P)

FOR SALE

FOR SALE

Philips E.M. 300
Electron Microscope

Tested by independent consultant and working to manufacturers specification. 70mm, 35mm and sheet film cameras. High resolution and tilting stages, comprehensive spares.

Enquiries to the Administrator, Sir William Dunn School of Pathology, South Parks Road, Oxford. Tel: Oxford 57321. 1203(L)

CONFERENCES

UNIVERSITY OF READING

A one-day meeting on 'Aspects of Xylem Differentiation' will be held on March 30 in the Department of Botany, University of Reading. Speakers will include Professor P. Gahan, Dr P. Denne, Dr R. Johnson, Dr R. Phillips, Dr J. R. Barnett. Chairman will be Professor R. D. Preston F.R.S. Further details and registration forms from Dr J. Barnett, Plant Science Labs., University of Reading, Whiteknights, Reading RG6 2AS. 1177(C)

AWARDS

LADY TATA MEMORIAL TRUST INTERNATIONAL AWARDS for Research on Leukaemia and Allied Conditions

Academic Year 1978-1979

The Trustees of the Lady Tata Memorial Trust invite applications for Awards (both predoctoral and postdoctoral) for research on leukaemia, in the Academic Year beginning October 1, 1978. In view of the affinity between leukaemia and other forms of neoplastic disease, candidates with programmes of research on any aspect of malignant disease which may throw light on problems of leukaemia will be eligible for consideration. The Trustees specially wish to encourage studies of the leukaemogenic viruses in animals, the epidemiology, natural history, and immunology of leukaemia.

Awards are open to suitably qualified investigators of any nationality, working either in their own institutions or in other centres abroad.

Awards are offered at rates appropriate to the age, seniority, and experience of the candidates, and to the stipends paid at the Institution at which the work will be done, with provision for annual increments, bench expenses and superannuation if required.

Awards are tenable for 1 year in the first instance, renewable up to a maximum of 3 years.

Further particulars and forms of application may be obtained by writing to the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London SW3. Applications must be submitted before March 31, 1978, and awards will be announced by the Trustees in June. 1207(N)

NATO ADVANCED STUDY INSTITUTE

on Optical Activity and Chiral Discrimination

to be held at the

UNIVERSITY OF SUSSEX, BRIGHTON, U.K.

September 10-22, 1978

The Institute surveys recent developments in the theory and the applications of chemical and physical differentiations between enantiomeric and diastereomeric substances, and of the chiroptical spectroscopic methods, including scattering and luminescence circular intensity differential studies as well as circular dichroism absorption investigations over the range from the vacuum ultraviolet to the rock-salt infrared region.

The principal invited speakers include:

Dr L. D. Barron	(University of Glasgow)
Professor D. P. Craig	(Australian National University)
Professor R. D. Gillard	(University College, Cardiff)
Dr A. Moscovitz	(University of Minnesota)
Dr F. S. Richardson	(University of Virginia)
Dr O. Schnepp	(University of Southern California, Los Angeles)
Professor G. Sznatzke	(Ruhr-Universität Bochum)
Dr I. Tinoco, Jr	(University of California, Berkeley)
Dr O. E. Weigang, Jr	(University of Maine)
Professor H. Wynberg	(University of Groningen)

Contributed papers:

A limited number of contributed papers and poster contributions will be included and abstracts of 200 words are invited for consideration.

Registration and Accommodation

No registration fee for membership of the Institute is required and a limited number of grants are available for residents of the N.A.T.O. countries to cover part of the travelling and maintenance expenses involved by membership. Application forms for membership and further information are available from the Director of the Institute, Professor S. F. Mason, Chemistry Department, King's College, Strand, London WC2R 2LS, England. 1176(C)

bhra

fluid engineering

is organising an International Symposium on

WAVE AND TIDAL ENERGY

to be held at Canterbury, England, 27-29th September 1978

Covering sources and characteristics of waves and tides; physical and mathematical modelling; energy calculations; economic considerations; environmental effects; power from ocean currents; ocean thermal energy; site selection; progress reports from countries now investigating or operating schemes; and related subjects.

OFFERS OF PAPERS ARE INVITED

Further details from the Organising Secretary, WTE, BHRA Fluid Engineering, Cranfield, Bedford, MK43 0AJ, England.

APPLICATIONS FOR GRANTS MULTIPLE SCLEROSIS RESEARCH

Applications are invited for Grants funded by the National Multiple Sclerosis Society of Australia for research related to Multiple Sclerosis.

Support will be provided for approved clinical or epidemiological work as well as for laboratory-based studies within Australia.

Applications from suitably qualified persons will also be considered for Post-Doctoral Fellowships.

Intending applicants for project grants should write for further information to:

Mr. S. J. Resch,
Chairman,
National Multiple
Sclerosis Society of Australia,
616 Riversdale Road,
Camberwell, 3124, Australia.

Applications close on Friday, March 31, 1978.

**RESEARCH
ADVISORY BOARD:**
D. R. Curtis (Chairman),
E. French (Vice Chair-
man), P. R. Carnegie,
J. F. Hallpike, B. A.

Cellulose ion exchangers should be spherical too

DEAE-Sephacel[®] is

DEAE-Sephacel[®]
Total capacity: 1.4 meq/g
Wet diameter: 40–160 μ m

The spherical form of DEAE-Sephacel gives you easy, uniform packing without the generation of fines. It improves your results because it reduces zone broadening and ensures uniform, high flow rates. DEAE-Sephacel is reproducible from batch-to-batch.

No precycling is needed because DEAE-Sephacel is ready swollen. Its controlled macroporous structure, which is almost completely independent of pH and ionic strength, gives high protein capacities and excellent recoveries.

DEAE-Sephacel is the only spherical cellulose ion exchanger.

Immunological Products

A package of new products from Flow Laboratories

Lymphocyte Separation Medium . . . 20 ml, 100 ml, 500 ml packs are available. No minimum order; excellent quality control ensures: density of $1.077 \pm 0.001 \text{ g ml}^{-1}$; a high yield purity and viability of lymphocytes and susceptibility to PHA stimulation.

Lymphocyte Storage Medium . . . for storage of lymphocytes at room temperature. This modified McCoy's 5A is supplemented with antibiotics, foetal bovine serum and HEPES buffer

RPMI 1640 powdered medium with HEPES buffer . . . RPMI and four other powdered media are now available containing 20mM HEPES buffer.

Human AB Serum . . . for human lymphocyte stimulation experiments. Human AB is claimed to be less blastogenic than heterologous serum

LECTINS

AS TOOLS FOR MEMBRANE GLYCOPROTEIN STUDIES

Phytohemagglutinin, 79-150

PHA is a partially purified extract that will agglutinate erythrocytes of all human blood types as well as those of rabbit, dog, cat, mouse, sheep and guinea pig. PHA also possesses the ability to initiate mitoses. Each lot is provided with erythroagglutination and mitogenic activity titers.

Peanut Agglutinin, 79-151

Peanut agglutinin agglutinates lymphocytes from mouse, rat, guinea pig, and man only after treatment with neuraminidase. Treatment with β -galactosidase reduces agglutination of neuraminidase-treated lymphocytes.

ALSO AVAILABLE:

A wide range of Lectins in free and agarose-immobilized forms and as FITC-derivatives:

Concanavalin A and Con A Salts
 Fucose Binding Protein (from lotus seed)
 Soybean Agglutinin
 Wheat Germ Agglutinin
 Ferritin-Concanavalin A (for Electron microscopy)
 Lens Culinaris Hemagglutinin A
 Lens Culinaris Hemagglutinin B
 Ricinus Communis Agglutinin—60
 Ricinus Communis Agglutinin—120

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width, so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Newly on the market		ix

At the beginning of 1978 a new copyright law came into effect in the United States. Single copying of *Nature* articles and letters for personal purposes is allowed under the legislation, as, under certain circumstances, is multiple copying for class-room use (see Sections 107 and 108 of the US Copyright Law). On the other hand, all other copying in the US is subject to restrictions. If copies are to be made for resale in any way, a written request must be made to us; if the copying is for any other purpose, consent is granted if the copier pays the appropriate fee to the Copyright Clearance Center, Inc., Operations Center, PO Box 765, Schenectady, New York 12301, for articles, letters, etc., bearing a code number at the foot of their first page. The fee for each copy of an article, letter, etc. reproduced is as indicated in the code. In all other countries, single copying for personal purposes and multiple copying for non-commercial class-room use is permitted but other copying requires written permission from us.

More and more people are finding JEOL gives them maximum capability—

...shouldn't you take a close look at what JEOL can offer

Top left: TEMSCAN. Total analytical capability in electron optics, including TEM, STEM, SEM, NDS and ELA.

Top right: JEM-100S. Cost-effective routine TEM with high performance, yet simple to operate.

Centre left: JSM-T20. The best routine, low-cost SEM available, with built-in micron marker and function checker.

Centre: JSM-35. Multi-purpose, high resolution SEM with total X-ray analysis capability.

Centre right: JSM-25. Routine, versatile high performance SEM with unique easy operation features.

Right: FX-Series. High performance and versatility for FT-NMR.

Truth at any price

GEORGE STEINER, in his recent televised Bronowski Memorial Lecture, asked "Has truth a future?" For he fears that there may be a fundamental incompatibility between man's hopes of justice and decency and certain categories of truth.

Steiner, whose lecture is published by the BBC at £1, remarks that an infatuation with truth-for-its-own-sake emerged in Greece and Greek colonies between the seventh and fifth centuries BC, and must be clearly contrasted with the pursuit of useful knowledge—an occupation of many times and many places. "The man prepared to risk destitution or ridicule in order to solve a quadratic equation or a paradox in logic is an Ionian or south Italian Greek in the age of Pythagoras and Anaximander, of Heraclitus and Anaxagoras. Those who today pursue abstract truths in the sciences, in mathematics, in philosophy, are heirs to his hunger."

But, continues Steiner, abstract thought and the pursuit of truth have had their detractors, even enemies. Mystics and irrationalists, dogmatists and supernatural revelationists all in their different ways see mathematics, science and other scholarly pursuits as of a lower order than knowledge revealed through ecstasy or a divine statement. Then there are the romantic existentialists, Blake, Wordsworth, Kierkegaard, Tolstoy and so on, for whom 'the values of ecstatic self-realisation, of moral goodness, of simplicity, even of absurdity are set high above those of mathematical-scientific truth'. Finally, there are the truth-is-not-neutral critics who assert that truth and logic is used as a class weapon of oppression. There can be found mathematicians and scientists, Steiner might have added, holding with unmistakable sincerity all of the above views.

Now, however, we are confronting a new challenge of a rather different kind, he claims. Some of the truths that we turn up or might be capable of turning up could be in conflict with ideals of social justice or even survival. We know, as an extreme example, that sometime in the remote future the universe will run down in some way or other, and that will be the end of us. This piece of information is tolerable to most people and does not lead to any great move to restrict cosmologists' freedom of action. But some things are much more immediate. Predetermination of the sex of the foetus, cloning, the contributions of heredity and environment—such matters are the stuff of present-day research and the results of this research could have immediate implications for the social system we know. Many would argue that we are within sight of revealing verities of a kind that society cannot handle, and that now is the time for a socially responsive science, scaled down to human needs. "Not the costly elitist chase after the esoteric and possibly destructive fact, but the arcadian pilgrimage towards self and community."

But it won't work, claims Steiner; partly because nation-states have now come to believe that future grandeur and security might depend on unrestricted investigation, but mainly because "the obsession with objective and abstract truth is imprinted on the western mind", and even if truth lies in wait for us with hideous snares, there will always be those who will press on. Bronowski, humane and learned

man, might have said that "if man's endurance as a more or less decent creature depends on leaving certain doors closed, then so be it", thinks Steiner. But the other point of view, that truth matters more than man, is "also possible".

This is not unfamiliar territory; for instance last August Sir Andrew Huxley was asking similar if more specific questions about research into the heritability of IQ, and nuclear physicists have agonised over morality and research for more than thirty years. But it can rarely have been raised in a more penetrating and cross-cultural way. Yet for all that, it is possible that however carefully balanced and scrupulously worded Steiner's argument is and however agonisingly he has had to choose to come down on the side of truth, even against man, the picture that he has painted of the emotive concept 'truth' is altogether too stark, and the choice between man and truth made much too clear-cut. If one were to ask most scientists how they view their profession, they might well say something about hoping to add to knowledge, or conceivably might talk about making falsifiable hypotheses or learning by trial and error. But the word 'truth' might never crop up. Partly this would be because of the debasement of it by the propaganda and publicity world. But more likely it would be because the spirit of scientific enquiry tends not to reveal truths so much as to answer some questions at the expense of raising others of a more fundamental character. For sure a question such as 'is it true that the sex of a child can be pre-determined?' may well be answerable in the affirmative in the foreseeable future, but such a question is more one of technique not an eternal verity. Steiner persistently conjoins mathematics with science in his lecture, indeed uses mathematics for the examples of the elucidation of the earliest truths, and this may well be a mistake. The rigorous logical consequences of mathematical enquiry have very little in common structurally with the results of biological enquiry.

Nor is this the only ambiguity that comes from too stark a portrayal of truth. Those scientist who think seriously about marking certain doors 'too dangerous to open' are by no means all committed to "putting the questing, autistic brain to pasture, while instinct plays" or even to an "alternative style of cerebration" as Steiner would have it. They still do recognisable research, sometimes highly esoteric; they still submit papers to journals, live with peer review and hope to outpace their rivals—in short they behave like other scientists, and if truth were the right word for it, they would equally be reckoned to be pursuing truth, but not necessarily truth at any price.

Many years ago scientists recognised some sorts of experiments with humans and animals as ethically unacceptable. The doing of such experiments might yield all sorts of valuable knowledge but at an uncertain expense of suffering or degradation. So 'truth' was retarded, but biomedical researchers are not the less dedicated to the pursuit of knowledge for almost universally honouring this ethical code. We may at present be groping towards a similar code for the protection of society, and just possibly in a hundred years time our successors may deem the world of learning to have been little hurt by it. □

Saudi Arabia and the travelling scientist

ONLY in the past week has the outside world come to hear of the particularly savage public executions in Saudi Arabia last November of a princess and her husband for, apparently, contracting a marriage contrary to royal decree. At least the couple were spared being stoned to death—a fate which befell three men in Saudi Arabia last year after they had been found guilty of sexual offences. The Islamic code of justice has harsh things in store for sexual transgressors, and Saudi Arabia is not, of course, the only country that operates such a code.

But why is this any special concern of the readers of *Nature*? Certainly we should be exercised when states interfere with the elementary human rights of scientists or when they tamper with the means of scholarly communication. But is this recent matter, however barbarous and seemingly unjust by our different moral and legal standards, any cause for scientists to take special interest in?

The answer is yes. Saudi Arabia is in the throes of a mighty transition, often described as a leap from the Middle Ages to the atomic era. Science, technology and medicine are playing an enormous role in effecting this change, and higher education—non-existent before 1947—is now open to several thousand students each year. What is more, Saudi Arabian interests are not exclusively in applied science;

there has been talk of a particle accelerator and rather more than talk about a major telescope. All of this has meant an increasing flow of Western scientists into the country to teach, collaborate and advise.

Such scientists have an easy and relaxed access to the Saudi intellectual community—easier, probably, than that of any other group, as they are not there specifically to sell equipment, buy oil or represent the delicately balanced interests of their home country. They thus have an excellent opportunity for quiet and honest conversations with hosts about the way that Saudi Arabia looks from the outside world and how decades of impressive achievements can count for little if there are not comparable developments towards at least the elements of a society that is humane and just.

Much informed opinion in Saudi Arabia would probably already concur with all this, but its hand would be immeasurably strengthened in pressing for change were the message to be repeated from the outside as often as possible. And there are several other countries where, equally, the travelling scientist can be a power for good in this way. Maybe we underestimate the influence that the global scientific community could have with its liberal attitudes and ease of access to people of influence. □

Medical education and biomedical research: uneasy equilibrium

George A. Silver, Professor of Public Medicine in the School of Medicine, Yale University, argues that medical education should be separated from research if the best doctors and research workers are to be produced.

AMONG the casualties of the upheavals of the 1960s, one of the most far-reaching has been the dissipation of unlimited faith in the benevolence of science and the efficacy of progress along with a loss of confidence in social institutions generally. Biomedical research and medical education have both suffered the consequences, although in different ways and to a different extent. There is dissatisfaction with the medical care system, a dawning recognition that not all diseases may be curable and scepticism of the motives of both medical educators and researchers.

A medical school dean writes (Sherman M. Mellinkoff *Johns Hopkins Med. Jour.* 141, 167; 1977): "Triumphs of the biomedical sciences have burgeoned exponentially. Nevertheless there sometimes seems to be a miasma of something between apprehension and gloom over the American medical schools of this decade. Seldom has medical education been subjected to so much criticism, ranging from valid to vicious, from thoughtless to mindless. It is as though success had earned no laurels but a handful of nettles." And he attaches a litany of the public and popular complaints, among which the outstanding are "... that medical students are deliberately selected or molded to be overly scientific and lacking in altruism" and that the schools "... pay too much attention to abstruse problems and neglect common ailments ..." both of which he considers false.

In searching for the culprit, if there is any, the questioning seems to centre on this intertwined relationship, the apparently indissoluble bond, between biomedical research and medical education. A measure of obloquy has in recent years fallen on Abraham Flexner, the educator whose report on medical education in the United States (*Medical Education in the United States and Canada*, Carnegie Foundation for the Advancement of Teaching, NY (1910)) is considered the platform from which modern medical education was launched. Although Flexner epitomised a tide then running and so gave his name to the course of events already in train, he should only bear responsibility for recognising the trend and helping establish a rational base for medical practice. He did propose the university as the locus for medical education and medical research as an important associated activity.

But 'research' in the early years of this century was not the research we know today. One must visualise Sir William Osler, observing patiently and critically, recording the natural history, symptomatology and autopsy evidence of disease as the prototype of the investigator of that day. There was only modest and inexpensive equipment in the laboratory for examination and study. In short, 'research' was essentially clinical study in a scientific style.

Now that we have a multimillion-multibillion dollar research industry fastened upon the medical education process throughout the academic world, we begin to have second thoughts. Examination of the medical research and medical education budgets for 1975, shows that while \$800 million went specifically for research, only \$368 million went into teaching and training in the academic institutions. Total budgets for the medical schools were twice this amount, including many other kinds of payments, but

research costs are heavy elements.

There has never been any secret about the fact that the goals of the research community have been to use the medical educational establishment to further its goals. "The simply stated goal of the NIH has always been to develop a science base for the formulation and solution of medical problems" (James A. Shannon *Jour. Med. Educ.* 51; 1976).

For the proponents of the doctrine of the union of research and medical education, the course is clear. "If the definition of the goal of medicine as the saving of life, the relief of pain and the prevention of disability is accepted, it then follows that the tight coupling of biomedical science and clinical medicine is the critical feature of the medical school" (Donald W. Seldin *Clin. Res.* 23, 280; 1975). And dilution of this bond is reprehensible: "[the introduction of community services] has had the effect of changing medical schools more and more into second rate public utilities . . . compromised as institutions for the education of students in the biomedical sciences." If biomedical research distorts medical education and medical education is a constraint on biomedical research, should the two be bound together? The international implications are far-reaching, in view of the world-wide imitation of the American design.

There are other voices. In a recent conference, some influential medical educational leaders expressed concern: "There are many signs that society is finding the medical profession too insensitive to health care", stated one medical school dean. Students seem to be selected, educated, engineered toward goals of scientific excellence that are only remotely related to the everyday needs of citizens. The participants were told that only 35% of faculty time was spent in basic instructional activities and they wondered if more time couldn't be devoted to teaching in order to reduce the phenomenal faculty to student ratio in this country. Ronald Christie, a dean, professor and clinical practitioner on three continents in a review of medical education world wide (*Medical Education and the State* DHEW publ. no. (NIH) 76-943 (1976)) expressed some doubts about the almost one-to-one faculty student ratio in the US, also pointing out that in Canada the ratio is one-to-three; in Australia one-to-ten and in the UK one-to-sixteen. Since these countries seem to graduate excellent doctors, on a par with the US product, the discrepancy—and the expense—is puzzling. The cost of medical education, per student per year averaging \$12,650 in the US when studied by the Institute of Medicine of the National Academy of Sciences, and ranging quite widely, from \$6,900 to \$18,650 (*Cost of Education in the Health Professions* IOM (NAS) DHEW publ. no. (HRA) 74-32 (1974)) seems to be twice as high as Canada's per student cost; three times Australia's and five times that of the UK.

If cost alone were the factor, one might hardly quarrel with the result, since the US is notoriously lavish in its expenditures. But the Christie note on the value of research as a concomitant of medical education, with which he heartily concurs, also queries the calibre of the research that is too often done to satisfy the requisite standard without providing the product required. He calls the mandarins to order in his comment that "Few of those involved in research in academic departments will admit even to themselves that their research is pedestrian or unprofitable . . ."

And a university president states (David S. Saxon *Jour. Med. Educ.* 51, 991; 1976) in connection with the shibboleth of academic tie as the *sine qua non* for medical education: ". . . these opportunities (for mutual exchange of ideas and research advances between the medical and general campuses) are rarely exploited."

A science administrator points out (William D. Carey *Science* 197, 825; 1977) how the tight bond between the academic, medical, educational and research areas may be

damaging to research activity: ". . . built-in inefficiencies and distractions are sapping the vitality of the research process . . . the dollars allocated to basic science no longer tell us much about the true levels of the research effort."

More grave a charge is levelled by a social scientist studying medical ethics in the practice of biomedical research (Bernard Barber *et al. Research on Human Subjects*. N. Y. Russell Sage; 1973). He quotes Merton, "The culture of science is, in this measure, pathogenic. It can lead scientists to develop extreme concern with recognition . . ." And he himself adds, ". . . we have presented evidence that the pressures of having to establish oneself in a competitive scientific community seem to have the effect of making these researchers engaged . . . less sensitive . . ." And again, ". . . our findings make it clear that it has some negative consequences for other important human values . . ."

If this is the attitude encouraged among researchers, should it prevail among students of medicine? Today's medical education makes the doctors much more dependent upon the technology of medicine, not only serving to reduce contact with and interest in the patient as a person, but also generating enormous expense in medical practice. Reinhardt ('Health Manpower Policy in the United States'. Paper presented at the University of Pennsylvania Bicentennial Conference on Health Policy, 11-12 November, 1976. Quoted in Somers and Somers, 'A Proposed Framework for Health Care Policies'. *Inquiry* 14, 115-170, June 1977) estimates that each physician in the US is the source of \$260,000 of medical expenditure each year.

Few rational people in this century would want to dispense with important, tested and proven advances in medical science and practice; nor would they propose discontinuing the admirable research efforts of this and other countries. The question at issue is, need biomedical research be so intimately, inextricably bound to medical education? It is not irrational to ask whether the medical educational process could not be carried on separate from, though with useful liaison to, the biomedical research efforts. The changed emphasis would allow a different selection, admission and process, less emphasis on technology and more emphasis on the patient as a person. It might help to redirect physicians in their practice, reduce the volume and cost of medical care, without increasing the mortality or disability rates among Americans. To be sure, some are already questioning the efficacy of medical care in reducing morbidity and mortality in any case (John B. McKinlay and Sonja M. McKinlay *MMFQ/Health and Society*; 1977).

On the research side, the separation might be beneficial as well. Investigators, choosing a career in which they could advance without competing for academic title, would not be split between the burdens of teaching, for which they never have enough time, and the necessities of the research activity, for which more constant and undivided attention is also demanded. Less money would be wasted in 'routine' research whose sole purpose is justifying the medical educational/research mix. As the students' role-models change, medical-practice careers will change. As Barber says (*NEJM* 295, 939; 1976), "Medical students are bright and ambitious; they have no difficulty ascertaining which subjects are taken seriously by the prestigious senior members of the faculty".

Biomedical research and medical education need to be separated to save them both from becoming isolated from the realities of the social setting, condemned to declining support in a climate of hostility in what should be their natural constituency. There is need for special attention to both. A medical education that glorifies research while ostensibly preparing students for practice will provide society with neither the best doctors nor the best investigators. □

Greek orthodoxy

The first of two articles commenting on the research policy and universities of Greece by E M Pantelouris describes the patriarchal and bureaucratic structure of Greece's higher education system.

WHY, one may ask, do 30,000 Greek students, representing nearly 30% of the student community of Greece, study abroad? Is this a vote against Greek higher education? Or are there just too few places for too many students? To describe the system is an answer in itself, and I shall attempt to do that here.

The aspiring Greek student cannot rely on the education provided by his or her six years of secondary schooling to secure a university place. Entrance is by written examination, conducted uniformly throughout the country, and to prepare effectively for these examinations, secondary school pupils commonly attend classes run by private cramming schools, which are a growth industry in Greece. Quite often, a young man or girl will spend a whole year after coming out of secondary school attending these 'frontisteria' before attempting, or re-attempting, the university entrance examination. Pressure is high, as the 1977 figures illustrate: slightly over 13,000 places were available for some 78,000 applicants (see Table 1).

This first hurdle over, the successful candidate embarks on a degree course that lasts as a rule four years (more for medicine and for some branches of engineering). Degrees are, rather general, with six or more subjects continued to the fourth year. Lectures are formal and *ex-cathedra*, a format aggravated by the relative absence of a large body of published books in science subjects, and the extremely poor library facilities. Textbooks prepared by the professor in charge of each course are produced and distributed free by the government. This is very helpful, as few textbooks can be published economically in Greek, but might fossilise lecture courses.

There is nothing comparable to the British 10:1 student-staff ratio. No average figure can be given, but however calculated, the ratio would be several times higher. The professor of a 'chair' is the only one officially entitled to lecture to students, except for one or two 'authorised' sub-professors (*ifigitis*). The rest of the staff are kept incommunicado, except for the laboratory sessions. It has been put to me that they are selected as demonstrators rather than lecturers: most of them still have no higher qualification than a primary degree. Teaching is thus concentrated in the hands of the professor.

Dr E. M. Pantelouris visited Greece as a Nature travelling fellow.

Table 1 Entrants by examination to university level institutions†, 1977-78

Law*	2,896] total 6,036
Economics*	3,140	
Literature, philosophy	1,145] total 2,030
Theology	100	
Modern Languages	785] total 4,329
Scientific and agricultural		
Medicine, pharmacy, veterinary science	1,017] total 13,412

*About a third of law and economics students are gainfully employed and hence in effect part-timers. For comparison, in the UK about 30% (212,000 including 49,000 of the Open University) of students—including postgraduates—are part-time
†Excluding physical education, teacher training and military schools

Table 2 An estimate of the number of Greek students abroad (before 1976)

Student population in Greece at university level	80,000
Total of Greek students abroad*	30,000
Annual student entry at universities abroad	6,000
Distribution of Greek students abroad:	
Italy	55%
UK	14%
France	8%
Germany	6%
USA	6%
Others	11%

*Based on applications in 1975 for foreign exchange for the purpose of financing full-time studies abroad

Academics and bureaucracy

Academic staff are also utterly dependent on the professor for tenure. Appointment to an assistantship lapses after nine years, unless a doctorate is obtained—an invitation to professors to grant internal doctorates to some to save them from redundancy. After a further six years, it becomes necessary to submit another thesis for the title of *hyphigitis* (or 'dozent'), some of whom may eventually be entrusted with a course or part of a course. Laboratory facilities, and acceptance of theses for such in-service internal degrees, depend in practice on the discretion of the professor, and reflect more his decisions about continuation of employment rather than any independent assessment of research ability.

Unavoidably this archaic system lowers the level of undergraduate teaching and prevents intellectual communication between staff and student. The students' response is disenchantment with the system, and the short term attitude that one is there just to get a degree of sorts, as nothing else

can be got—unless it is the intensive politicisation reflected in the slogans that completely deface the walls of university buildings.

Of course, students and staff are aware of the shortcomings of the system, care about it, and agitate. And it must be stressed that this system is breached by commonsense in many departments, where younger professors begin to bring to bear the approach under which they themselves trained abroad in the Anglo-Saxon world or elsewhere. But there remains in all cases the stranglehold of the greatest scourge of Greece: bureaucracy. If a professor wishes to authorise his second-in-command to give a course of lectures, the move has to be approved by somebody 'at the ministry', who will first calculate whether the lecturing load of the professor entitles him to such help—because an honorarium will be paid. Similarly, after an annual grant has been allocated, the department still has to submit for approval a list of purchases before they can be effected; so that work can be delayed for months because a chemical cannot be purchased outright. I have come across cases where the professor pays from his pocket to save the situation.

Here we come to the real key obstacle to reform: the tradition by which university regulations are nearly uniform for all institutions, and acquire their force through the ministry and publication in the government *Gazette*; that is through a centralised extra-university and political organ. University independence is restricted; and in abnormal periods—of which fortunately the present is not one—professors are dismissed or appointed by the will of the minister.

Yet paradoxically, the key to improvement lies with the government. If matters were left to the ability of universities to renew themselves, the impression is that the older Athens institutions would remain static, although the outcome could be different at the newer University of Thessaloniki. In one institution with some 25 professors I was told that only a handful favour reforms. To understand these attitudes it has to be taken into account that the most influential groups of professors are those in fields such as medicine and engineering, where titles of professor, *hyphigitis*, and so on are springboards for lucrative private practices, consultancies, and membership of innumerable committees.

A law is promised to replace the 'chair' system with a so-called sector system. Students and staff understand this to mean independence of university teachers in matters of lecturing and marking in their speciality, choosing their own research and participating in the running of academic affairs. The long incubation of the law, however, is giving rise to suspicions that the sectors will emerge as nothing more than groupings of related chairs as before.

It is to be hoped that the government may in the end come down on the side of actual, not simply cosmetic, changes that might enable Greek universities to gradually become something beyond mass producers of graduates, and rise to be schools for researchers. This they are definitely not at present.

For example, facilities cannot be expanded speedily, under the current pressure for places, to achieve overall a better staff-student ratio and to make possible the general adoption of more useful working methods. It should however be feasible for science faculties to introduce research-oriented streams for their third and fourth year students. Entry into these streams would be by merit as judged by the student's performance in the first two years, and the numbers accepted could increase as more facilities become available. In this stream, subjects would be dealt with in depth, and tutorials, dissertations and research projects would replace set practicals and lectures.

Academic staff should be given a

greater role, not indiscriminately, but in recognition of higher qualifications obtained outside the employing department, that is, under present circumstances, in reputable centres abroad. Leave of absence for the purpose should be available.

Furthermore, non-professorial staff should be free, indeed encouraged, to seek, individually or in groups, research grants and thus to participate in government plans to stimulate problem-oriented research.

What has been said is sufficient to explain the annual migration of aspiring students. As undergraduates, they seek a place that was denied them at home. Naturally, most go where entry to a university is—or rather was—an uncomplicated and undemanding business. Thus more than half of them jump from the frying pan of the Greek into the fire of the Italian system. Even Romania has been recently invaded, and is now, like Italy, taking steps to reduce numbers (Table 2).

As far as postgraduate studies are concerned, it would be an excellent thing if Greeks went abroad so as to keep, on their return, national research within the mainstream of world science. In practice, the potential benefit to the country—and to themselves—is reduced by the haphazard acceptance of places anywhere, without due regard to the subject of the research degree, and the suitability of accepting institutions. However, despite its wasteful and unfair character, the process is creating a large pool of people trained in a variety of spheres. It is another matter whether Greece can

make rational use of them.

Reforms

Against this background, the determination of the former and the present governments of Mr K. Karamanlis to reform the educational system becomes better understood.

Compulsory school attendance is being extended from six to nine years, the first six in a primary school and the other three in a junior secondary. In this junior secondary, classics will be studied in modern Greek, thus allowing a shift of emphasis from grammar to content, and making an important saving of time for modern subjects.

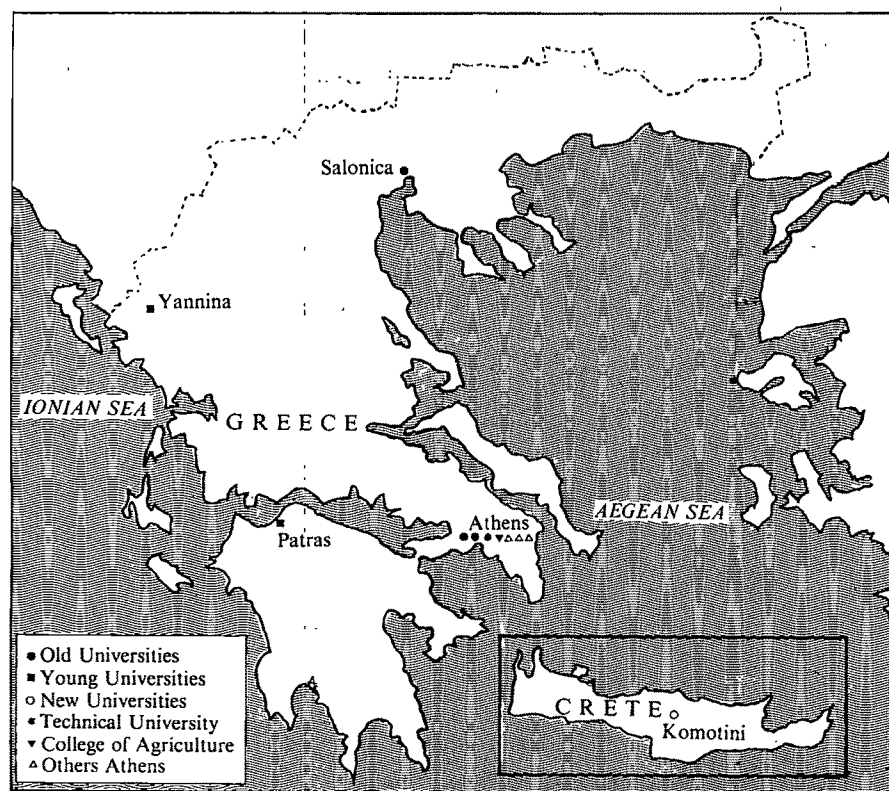

After completion of the junior secondary course, young people will sit examinations for entry to a senior secondary school of either an academic, or a technical-vocational stream. On emerging from the academic secondary, people will be entitled to a university place without entrance examinations (this will take effect as from 1980). Pupils who fail to gain entrance to either type of senior secondary will be enlisted for shorter vocational courses.

Putting such changes into speedy effect is no mean task. Change is proceeding apace, and is accompanied by the appointment of new teachers and the building of new schools at the rate of 1,500 classrooms per year. The demotic form of modern Greek has in the meantime been introduced throughout the educational system. New and better schoolbooks have been produced in record time. Investment of some \$250 million in technical education has just been announced by the government.

At the level of higher education, the young universities of Patras and Yannina are expanding steadily, and two new institutions are being established in Thrace and in Crete. There should, eventually, be sufficient places within the country for most qualified finalists of the senior secondary schools.

Some serious criticism can be made of the way in which the new universities are being set up. Under local pressure, the various faculties of the University of Crete will be scattered throughout the island, making impossible the creation of a coherent campus.

It is also unfortunate that planning of the new universities has been entrusted to detachments of professors from the old institutions. Although some of these people are very distinguished, the risk remains that the new establishments too will be made in the Bavarian style of the old ones. A unique opportunity of introducing creative diversification and innovation into the system will have been missed. Is it too late? □

Canada's nuclear visitor

"THERE are thousands of manmade objects in space. I suppose roughly half of them belong to the Russians and the other half to the Americans. . . . I know there are things up there. I know they are going to fall someday, but I don't want to hear about it until it looks as though they are going to fall in my country. When you hear that, call me again!"

Such was the breezy comment of Canadian Prime Minister Pierre Trudeau on the crash, or, to quote Montreal Radio, "unplanned re-entry" of Kosmos-954. This attitude seems typical of the understatement with which all parties concerned have treated the first cosmonuclear disaster, an attitude which *Pravda* described as "realistic" and "undoubtedly due to the climate of international detente".

Fortunately for the cheer-merchants, the errant satellite descended in an area where, according to Colonel Donald Davidson who led the search team "there is no specific indication" of people save "the odd trapper or trapper . . . a few solitary souls who normally work the area". The specific location of the debris "12.8 km northwest of the landing strip" about 300 km from Baker Lake and 1,500 km northwest of Edmonton brought home to the world at large that Canada had just abandoned the mile. Even the general vicinity of the impact was seized upon by the joke-makers ("Great Slave Lake, eh? Maybe it thought it was heading for the Gulag Archipelago!"). Even the fact that the satellite finally landed in an area with sufficient uranium deposits to give false readings on the search instruments was not without its special brand of irony.

But leaving aside both humour and grim speculation on the devastation which might have resulted had the

satellite fallen further south, a number of questions remain unanswered. Why did debris reach the ground at all, when, according to Tass, the nuclear power unit was designed to be fully destroyed and burnt on re-entry. And,

if the fail-safe construction of the craft was lacking in this respect, would such a burn-up have been, as claimed, without radiation hazard? How safe, indeed, is the debris? (The two members of the search team who found the impact crater have been removed to University Hospital, Edmonton, and the other members to the hospital in Yellowknife.)

More important, what is the procedure for notifying countries that a nuclear satellite may be about to fall? In spite of an opposition hammering, the Canadian Minister of Defence Danson and Secretary of State for External Affairs Jamieson seemed fairly content with the manner in which notification came largely through Washington. However, Canada

is a somewhat special case, being a participant in the US Space Detection and Tracking System via the optical facilities at Cold Lake, Alberta, and St Margarets, New Brunswick. (Canada is also associated with the USA in the NORAD early warning air defence system. Although this relates primarily to manned aircraft attack.) In return for this contribution to the tracking system, Canada automatically receives from the USA all relevant data on space objects. Hence the routing of the warning via Washington is at worst only a slight blow to Canada's *armour propre*. What, however, would have been the procedure if some other target country were involved? Would the message always go via "hotline" to Washington, or perhaps via the nearest "major" power? What then would be, for example, Dublin's reaction to such a warning being routed via London?

International agreements already provide for the search and disposal of crashed space-craft—the craft is to be returned to its owner, the target country reimbursed for damage and search costs. (Will the US participation in the Canadian search cause difficulties here?) What does seem to be lacking is a proper notification procedure, both of spacecraft in distress and spacecraft carrying potentially hazardous material. It would presumably not be impossible to extend the treaty banning nuclear weapons from orbit to nuclear fuel units, or failing an outright ban, to make all such "nuclear" launches notifiable to some central authority. Secretary of State Jamieson and Prime Minister Trudeau have already been discussing possible international talks on the problems arising from the aftermath of Kosmos-954. If these should be forthcoming and fruitful, one could well agree with *Pravda* that this unfortunate incident has, after all, turned out a triumph for detente.

Vera Rich

US agencies to study links between saccharin and cancer

SACCHARIN is to be investigated by the US Food and Drug Administration and the National Cancer Institute, who are to conduct an epidemiological study of 9,000 people in an attempt to determine whether there is a connection between saccharin and bladder cancer.

The dietary habits of 3,000 people diagnosed as having bladder cancer will be compared against those of a randomly-selected 6,000 controls. The study is expected to last 18 months, and to cost \$1.3 million.

Last November, Congress announced a moratorium on proposed legislation that would ban the use of saccharin

because of its suspected link with bladder cancer. Congress also agreed to allocate \$1 million for studies on the safety of saccharin, \$750,000 of which is for the epidemiological survey.

Congress's action followed the publication in October of a report on cancer testing technology and saccharin from its Office of Technology Assessment, which concluded that although there was evidence that saccharin is a potential cause of cancer in humans, there was no reliable quantitative estimates of the risk of saccharin to humans.

According to the OTA report, epidemiological studies of human experience carried out so far have not been sensitive enough to determine if saccharin is a carcinogen when injected. □

NSF encourages more university/industry collaboration

In a move carefully timed to coincide with the opening of Congressional hearings on its budget application for the year 1979, Dr Richard Atkinson, director of the US National Science Foundation, announced last week that the foundation plans a major expansion of its support for research projects carried out by joint university/industry groups.

No new funds are to be allocated in the NSF budget for such projects: they will be required to compete for support with other regular grants' applications.

Dr Atkinson said, however, that joint projects would be given more active encouragement than in the past, including a major publicity campaign aimed at both industry and universities. Industry was less willing than in the past to risk money on basic research and long-term goals, and was increasingly focusing on product improvement. "Given these trends, the nation is becoming more dependent than ever on universities and colleges to provide the basic research for new technologies and products," he said.

Last week's move follows past criticism from Congress that industry has not been able to compete for research funds on the same basis as university research scientists, a point heavily stressed, for example, by Senator Edward Kennedy during last year's authorisation hearings.

One outcome has been a recent decision by the National Science Board to amend its language covering applications from industry for such grants. Previously it had stated that these would only be considered under certain circumstances, namely if the research was of national importance, or if industry was able to provide unusual expertise or instrumental capability. The new wording is more positive, indicating merely the type of applications that will not—rather than will—be considered.

A particular point stressed by NSF officials is that the delay before pay-off from basic research is a deterrent to industry investing in this area, and that NSF funding might help redress the situation, for example, allowing those scientists who have joined industry because of a lack of jobs in more academic settings to carry out basic science projects.

This argument is not likely to carry much weight with industry, which has recently been telling the government that basic research is a federal responsibility, while development activities should be left to the private sector (a message reflected in the proposed shape of R & D funding within the President's 1979 budget request to Congress).

The sector which is likely to respond much more to the NSF's rallying cry are the small, knowledge-intensive, high-technology firms—such as those distributed around Boston's famous Route 128—many of whom have been experiencing financial difficulties in recent years.

Such firms, however, are rarely interested in basic research as such, even in the long-term. Their main concern—for which there is at present a lack of money—is finding ways of turning a good idea into a marketable product. And this is where, in practice, NSF support will be in greatest demand.

David Dickson

Argentina: US National Academy of Sciences to send delegation

THE Human Rights Committee of the US National Academy of Sciences is to send a small delegation to Argentina next month to investigate charges of repression against scientists.

The delegation, which will also visit Uruguay, will consist of Dr Christian Anfinsen of the National Institution of Arthritis, Metabolic and Digestive Diseases, Nobel Prize Winner in 1972 for work on the structure of proteins, Dr Robert Perry, of the Institute of Cancer Research in Philadelphia, and a member of the NAS staff.

During a ten-day visit to Buenos Aires and Montevideo, the delegation will talk with both scientists and government officials about scientific co-operation with the US, and about the situation of scientists in the two South American countries.

The NAS delegation's visit follows a recent trip to Argentina by Mr Emilio Daddario, president of the American Association for the Advancement of Science, and until recently director of the Office of Technology Assessment.

Mr Daddario said in Washington last week that the actions of the security forces in Argentina had, with a few exceptions, "made a shambles" of scientific freedom, and that reports reaching the West of repression against individual scientists were not exaggerated.

Referring to moves by western scientists to boycott the International Union Against Cancer congress, due to take place in Buenos Aires in October, Mr Daddario said that many of the scientists he had spoken to in Argentina felt it important to maintain contact with their colleagues in other countries, particularly since many of them lacked funds to travel to conferences and meetings abroad.

However he also said that government officials had asked him about the attitude of foreign scientists to the cancer congress, and that he had the impression that they were concerned to appear to maintain normal international relations with the scientific community.

Meanwhile moves are gaining momentum in the US to boycott the congress in protest at the treatment of scientists in Argentina since the army came to power in March 1976. Since that date, many scientists have been reported to have been arrested or abducted without formal charges.

Last month at a meeting of American Cancer Society Research professors in Phoenix, Arizona, all 39 present found that they were unanimous in their individual decisions not to attend the congress if it is held in Argentina as planned.

France falls out with Pakistan over reprocessing

PAKISTAN'S reaction to the latest move of the French government to modify the accord of 1976 on building a nuclear reprocessing plant, has been quite firm and unequivocal. In view of strong public statements there appears little chance that the Pakistani government will succumb to any retraction from the agreement, or soft-pedalling. A Foreign Office spokesman in Islamabad said that the government would not accept any change or modification in the agreement already reached.

The French want to substitute a co-processing plant for the planned plutonium reprocessing plant to guard against separation of plutonium that could be used in explosive devices. A co-processing plant can only reprocess the spent fuel once or twice for use in reactors and it does not produce plutonium. Pakistan's nuclear 'think-tank, however, has plans for using plutonium, particularly when it develops its fast breeder programme.

Mr Munir Ahmad Khan, the Chairman of PAEC (the Pakistan Atomic

Energy Commission), when asked for the rationale behind the timing of the setting up of the reprocessing plant, explained that PAEC wanted to synchronise the installation of the reprocessing plant with the commissioning of a few more reactors, but that for various reasons the reactor programme is running behind schedule. Mr Munir Ahmad explained, however, that the reprocessing technology is highly sophisticated and takes longer to set up than a reactor.

His team would like enough time to acquire the necessary experience in reprocessing technology for its optimum use. Hence, the hurry for the reprocessing plant.

At Chashma, the site of the proposed plant (plus a 600 MW reactor), the foundation concreting is in progress in anticipation of things ultimately working out as planned.

In his recent address to the Institute of International Affairs in Karachi, Mr Munir Ahmad explained the technical and economic reasons for building a

reprocessing plant in a country like Pakistan—which is planning on deriving almost half its energy supply from nuclear sources by the end of the century. Even the 2,000 MW from the big earth-filled Tarbela dam, he claimed, would be insignificant in filling the country's energy gap. And oil-fired power stations were becoming less viable, especially as Pakistan had so far struck almost no oil or good quality coal. So, the only option, according to Mr Munir Ahmad, would be the nuclear one.

His view is that in the overall nuclear fuel economy framework, reprocessing of used fuel plus plutonium is inescapable. Jacques Couture, sales manager of the reprocessing division of the French company, Compagnie Generale des Matières Nucleaires, has not missed his opportunity to blow the re-

processing trumpet. He has said that "with a typical light-water reactor which needs about 180 tonnes of natural uranium a year, the annual saving will be at least 40 tonnes, or even 70 tonnes if the plutonium recovered during reprocessing as well as the uranium is recycled." In fast breeder reactors, the fuel is some 20% plutonium oxide in uranium oxide, and the nuclear expert's view here is that a co-processing plant that cannot deliver plutonium is, therefore, not of much value, seen in that context.

Mr Munir Ahmad was vehement in his address on the topic of proliferation. He said that the safeguard imposed by IAEA had been fully incorporated in the agreement and that the French had imposed some additional safeguards. He saw no valid reason for the scepticism which had

been shown, and thought it might not be unfair to conclude that the motive for changing the agreement was to deny a developing country a useful, sophisticated technology of future.

Pakistan has sizable deposits of uranium and thorium-bearing minerals. Pakistani scientists are exploring the possibility of exploiting the indigenous sources of thorium in a thorium-uranium-233 cycle in fast breeder reactors, for which plutonium is essential.

The French have developed a proliferation-free uranium enrichment process—a chemical exchange method—but it is unlikely to be commercially viable for another decade or so. Likewise, the French concept of the co-processing plant has yet to be commercially accepted as it has not been tried in any other country.

Azim Kidwai

Europe's nuclear circus

PLENTY of shadow-boxing went on at last week's open discussions on nuclear energy organised by the European Commission, with no side quite hitting home but nevertheless a lot of energy expended. The proceedings were launched by news of an accident at one of Belgium's nuclear plants on 13 January. The accident was made public by the Environmental Protection Society who claimed that 80 people were contaminated by radium-131 and that the affair had been covered up by government authorities.

The news caused quite a scare in Belgium, but was ridiculed by speakers at the nuclear debate, doctors, and the director of the Tihange plant near Liège, where the leak occurred.

The so-called 'father of the H-bomb', Dr Edward Teller, a leading US nuclear physicist at the Hoover Institute for War, Revolution, and Peace, Stanford, California, told the nuclear hearings panel and an audience of several hundred that he was 'more alarmed' at the kidnapping of Baron Edouard Empain in Paris by terrorists, than by the Belgian leak. The Hungarian-born scientist claimed that he had been exposed to more radiation when he flew over Europe to be present at the hearings.

The state-run electricity company, responsible for the Tihange plant, put the figure of people involved at between 30 and 60. Director Robert Van den Damme said that no members of the public were involved during the accident which happened during an annual maintenance check. He said that workers ignored the leak until the job was done. Six people had

to be examined by doctors, who they said had been contaminated by 100 millirems of radium-131. They added that the maximum tolerated dose was 3,000 millirems for 13 weeks before the possibility of thyroid cancer occurred.

The Friends of the Earth argued that the principal issue was one of disclosure; that the authorities should have made the accident public and that their natural reaction had been to conceal it. But Mr Van den Damme denied that the affair had been hushed up. He said that the leak had not escaped from the plant and had therefore done no damage to the environment or the surrounding population. "It was not worthwhile to publish information about something that did not happen".

"If there is a leak, let's hope there are some terrorists in the area!"

The news did manage to give the Commission's nuclear hearings more relevance. The session ended after three days of heated debate between the supporters of nuclear energy and its critics. The highlight for many was described as a "confrontation" between two old debating partners, Robert Jungk, an Austrian futurologist opposed to the use of nuclear energy, and the controversial Dr Teller.

The theme of the session 'Economic growth and energy options: implications for safety, health and environmental protection', considered the problems of terrorist activities and the proliferation of nuclear weapons. Jungk argued that increased security measures to guard against the two problems could lead to centralisation and therefore police states. He said that this was a form of mental pollution that was not acceptable and advocated the immediate suspension of the nuclear energy programme.

Dr Teller hit back by describing what he termed as the worst possible pollution, that of poverty. He argued that the developed countries should devote their energy to developing nuclear power. He said that oil should be given to the third world to enable it to develop, whereas nuclear power was economically and structurally beyond its reach. And he put paid to terrorists by theatrically declaring that "the only way to get rid of terrorism is to get rid of terrorists".

The debate at least guaranteed a full house. EEC energy commissioner Guido Brunner made no final assessment of the findings of the hearings. Critics claim that there was never an intention of altering the Commission's approach to energy policy as a result of the debate.

Patricia Kelly

Polish censorship

COPIES of the Polish censorship regulations and instructions for the period February 1974–February 1977 have recently become available, via the unofficial "Social Self-Defence Committee" (formerly the "Workers' Defence Committee").

The subjects of banned articles during this period included: reports on industrial pollution of the environment, criticism of the bill on psychiatric medicine, information on the carcinogenic properties of PVC, discussion of the backwardness of scientific education in comparison with the West, errors in the selection of candidates for higher education, and data on the type of parasites afflicting Polish cattle.

The standing "Notes and Recommendations of the Central Office of Control of the Press, Publications and Entertainment" specifically prohibited publication of information on chemical hazards in industry and agriculture, work safety and hygiene, alcoholism, the Katowice mine disaster, and the purchase by Poland of production licences from capitalist countries.

Vera Rich

US soldiers in cancer study

THE US Department of Defense has promised to undertake a "crash programme" to examine the records of military personnel exposed to nuclear weapons tests in the 1950s to see if they provide evidence of any abnormal incidence of cancer. The promise was made by the deputy director of the Defense Nuclear Agency, to a House sub-committee on health and the environment during the course of public hearings last week on the dangers of low level radiation.

The sub-committee has been particularly concerned at evidence suggesting an abnormally high incidence of leukaemia among the 2,235 soldiers who took part in manoeuvres after a 45-kiloton test shot, known as Smokey, which was detonated in the Nevada desert in 1957.

A study of the possible carcinogenic effects of radiation on those involved is being carried out by the Center for Disease Control, whose director, Dr William H. Foege, told the sub-committee that the eight reported cases of leukaemia among the 2,235 was "out of the normal range".

Earlier Dr Karl Z. Morgan, who at the time of the test shot was director of health physics at the Atomic Energy Commission's Oak Ridge Laboratory, told the committee that his staff had been unable to retrieve scientific measuring equipment after

the shot because of "residual contamination". He had "no doubt whatever" that this radiation had caused the leukaemia now found in those who had taken part in the manoeuvres.

Dr Morgan, who is now a professor at the school of nuclear engineering of the Georgia Institute of Technology, criticised scientists who refused to accept evidence that there is no safe level of radiation, and that any dose, however small, can cause leukaemia and other forms of cancer.

"One of the many problems we face today is that many scientists have accepted the threshold hypothesis as a cardinal law and have lived with this hypothesis so long that they have become staid or petrified in their thinking. Now they cannot believe or accept the fact that the threshold hypothesis is wrong", Dr Morgan said.

David Dickson

Brothers in human rights test case

THE cyberneticist Gol'dshtein brothers—Grigorii and Isai—of Tbilisi, first hit the "human rights" headlines in 1975, when their exclusion from the Tbilisi Conference on Artificial Intelligence led to a confrontation between the international conference committee, who urged their admission, and the Georgian hosts. The brothers are now, once again, involved in what may prove to be a test case—Grigorii has been arrested, and Isai has been threatened with arrest on the charge of parasitism and "malicious evasion of socially useful work".

The charge of "parasitism" (being without visible means of support) was brought last year against refusenik Iosif Begun, who was sentenced to two years exile in Siberia. The authorities refused to acknowledge that he had

any means of livelihood, since his current occupation—teaching Hebrew—was not a recognised profession. The Gol'dshtein brothers, however, until their dismissal from the Mendeleev Institute of Metrology in 1971, had been earning 600 roubles (£300) per month each. Since the minimum wage in the Soviet Union is 60 roubles per month, the Gol'dshteins have managed to convince the authorities that they have been living on savings lawfully laid by from their earnings. Nevertheless, it is claimed, they are evading their responsibilities by failing to undertake socially useful work.

Both brothers were dismissed from their Institute in the routine manner, following their application for an emigration visa—an application which was refused on the familiar grounds of access to secret information. Unlike most refuseniks, they have now been "offered" jobs commensurate with their academic status, Grigorii in October 1977 and Isai in January 1978. These jobs, however, are at the "closed" Institute of Explosives Research in Tbilisi, where all work is potentially secret, and both in turn have refused to accept the offers.

On 17 January, Grigorii was arrested, and was released ten days later on a written undertaking not to leave Tbilisi. His trial is expected "perhaps in two to three weeks". On 19 January, Isai received an ultimatum from the police, that unless he finds a job within a month, he too will be arrested.

The Gol'dshtein brothers are so adamant in their desire to emigrate to Israel that in 1972 they unilaterally renounced their Soviet citizenship. Clearly, they are hardly the loyal comrades one would expect to find working in a secret institution. The jobs proposed for them are, they feel, yet another means of preventing their emigration.

Vera Rich

New threat to helium reserves

A demand that "all appropriate measures" be taken to conserve rapidly-diminishing supplies of helium for potential future use has been made in a report published last week by a committee of the US National Academy of Sciences. The committee, which was set up last autumn to provide the administration with independent advice on the politically-sensitive issue of helium conservation, suggests that there is "a strong case for building a substantial government-owned strategic reserve of helium". It also condemns the present venting of separated helium into the atmosphere by natural gas-producers.

Most scientists know helium merely as the second lightest element. Some have used its properties as a gas to fill meteorological balloons; others have more recently exploited its superconducting properties at temperatures close to absolute zero—where it remains in liquid form—for experiments ranging from nuclear fusion to the superconducting magnets that will be used in Fermilab's new energy saver/doubler.

But although current applications remain relatively limited, helium has become a major headache for the US government. Reserves of helium-rich natural gas, from which helium can

be extracted many times more cheaply than from air, are known to be very limited and, at current extraction rates, rapidly diminishing.

Awareness of a potential shortage of helium dates back to 1960 when the administration, with one eye on future federal needs for both defence and space research projects, passed a Helium Act. Under the terms of the act four companies were contracted to separate helium for storage from natural gas; the conserved helium was stored in the partially depleted Cliffside natural gas field near Amarillo in Texas, which at present contains about 39 billion cubic feet (bcf) of the gas.

But the act turned out to be an embarrassing and expensive mistake. With the run-down in both defence research and the space programme at the end of the 1960s, demand for helium dropped dramatically below expected levels—by 1971 the total market demand for helium was only half what had been predicted—with no indications that the situation would improve in the near future. The government's problems were compounded by the fact that private suppliers were able to offer helium at much lower prices than the administration.

The net result was that sales of helium by the Bureau of Mines in 1971 were lower by a factor of six than had been predicted. And the massive federal investment in conservation measures had resulted in an annual bill in interest charges alone of over \$20 million, with sales averaging only about \$1 million. One reaction was the immediate termination of the contracts with the four private suppliers—action which has resulted in lengthy litigation still making its way through the courts. Since then, natural gas producers have been venting helium either directly or indirectly into the atmosphere. And there have been growing demands from Congress that the whole issue of helium conservation should be looked at more closely, with an eye to new legislation replacing the 1960 act.

Last September the appropriation committees of both the Senate and the House ordered that a study of the present situation, with recommendations about possible new legislation, be carried out jointly by the Department of the Interior's Bureau of Mines and the Department of Energy (then the Energy Research and Development Administration). In their turn, these two agencies, which had also brought in the Department of Defense and the National Aeronautics and Space Administration (NASA) as two of the largest helium-users, decided that an assessment of the situation should be obtained from an independent non-

government organisation, namely the National Academy of Sciences.

Last week's report is the result of this study, carried out in only a few months by a specially constituted committee of the National Research Council (and taking into account the results of a public hearing on helium conservation measures held in Washington in November).

The committee's report is unequivocal and, at times, outspoken. "Obscured from public view by current dilemmas associated with energy supply and an unstable economy, public policy for the management of the nation's resources appears inadequate and inflexible" it says.

The committee points out that almost 96% of the world's resources of helium-rich natural gas is to be found in the US, and that with current rates of extraction, these are expected to run out within 20 or 30 years. Furthermore although current annual demand is only about 1 bcf, this figure is likely to be considerably higher by the middle of the next century, with potential applications in fields such as fusion and gas nuclear reactors, laser-based missile defence systems, and advanced energy conversion cycle.

"It is clear that even the maximum possible helium conservation programme will only buy time in which to adjust to the extraction of helium from air as the sole source" the committee says. It agrees that as a result of earlier conservation policies there is at present enough helium stored to meet federal requirements into the next century, but writes that "the case for helium conservation is long-term based on the interest of future generations . . ."

The report also points out that there is, at present, little market incentive for conservation of helium by private producers. It therefore suggests that the government contemplate taking "an aggressive role to resolve the legal and market uncertainties currently discouraging helium conservation."

Although the conclusions of the NAS report coincide broadly with the views of the government agencies

which commissioned it, they are likely to put a more subdued case in their own report to Congress, which is expected to be delivered within the next few weeks. Administration officials agree, for example, on the need to stimulate private industry's interest in helium conservation—but they feel that by concentrating on the the situation of supplies of helium-rich gas, insufficient attention has been given to the potential for extracting helium from ordinary natural gas.

Furthermore there is a feeling that the NAS report may have been too optimistic in its predictions of future demand for helium. For example, the report quotes a prediction by the Argonne National Laboratory that by the year 2050 the annual requirement for helium from fusion reactors and superconducting energy storage alone will be between 10.4 and 15.4 bcf. In contrast, information gathered from government agencies indicate that consumption in 2030 will probably be between 3 and 8 bcf.

The agencies, which have been asked by Congress for advice as to possible government action and future legislation, are therefore unlikely to recommend the renewed stockpiling of helium, at least not in the near future. Dr Ray Munnerlyn, who is responsible for helium policy at the Department of the Interior, said last week that in the present circumstances, he would personally be opposed to a recommendation that Congress should renew its helium purchases.

David Dickson

Erratum

We would like to apologise for the errors which slipped into the article 'Dioxin meeting recommends cancer study' on page 202 of 19 January issue. They resulted from dictation over the phone and subsequent editing and are amended as follows. The first sentence of the first paragraph should have begun: "Since the release of the tetrachlorinated dibenzo-p-dioxin (the isomer 2,3,7,8 tetrachlorodibenzo-p-dioxin) . . ." The company referred to as the Doll Chemical Company is in fact the Dow Chemical Company and Dr Rodolfo Saracci is at the Unit of Epidemiology and Biostatistics, not Immunology and Biostatistics as reported. The two groups from the University of Wisconsin and the Dow Chemical Company, which the article claimed reported animal studies to test the carcinogenicity of dioxin, were not in fact present at the meeting; their work was discussed in their absence.

correspondence

Catastrophe theory reply

SIR,—This is a reply to a number of recent letters (*Nature* 270, 381–384 and 658; 1977) attacking our article (Zahler & Sussmann *Nature* 269, 759; 1977) on applied catastrophe theory. Many of these cite applications in the physical sciences to rebut our criticism; but as we were careful to state repeatedly in our paper, our discussion applied only to models in the biological and social sciences. In a more specific complaint, the respected mathematician John Guckenheimer asserts that we ignored recent work of Kozak and Benham on denaturation (Benham & Kozak *J. Theor. Bio.* 63, 125; 1976), where the Maxwell convention, not the delay rule, is used. The effect of this change, however, is to remove the cusp, and thus the catastrophe theory, from the analysis. Dodson's letter gives another reason why catastrophe theory should not apply to denaturation.

A number of writers defend Zeeman's embryology paper (Zeeman *Lectures on Mathematics in the Life Sciences*, 7, 69; 1974). The meaninglessness of this paper's "first-order" quantitative results will be explained in Sussmann & Zahler *Synthese* (in the press). Guckenheimer complains that our discussion of evidence is misleading. We printed Zeeman's statement verbatim and then five facts which no one has disputed (with one minor exception; see below). Despite Guckenheimer's attempt somehow to separate confirmation of a model from confirmation of that model's predictions, we feel that most readers will agree that our assessment, and not Zeeman's, is supported by the facts.

Zeeman writes that our article ignores a rigorous version of his main theorem published elsewhere (Zeeman *Proc. Int. Cong. Math. Vancouver* 2, 533; 1974). We criticised the first proof for unjustifiably singling out the time-axis. The second proof adds an assumption, not mentioned in the paper addressed to biologists, which declares that the time-axis is special—postulating what cannot be proved. Ignoring all the other faults we found in his proof (which are not repaired by the new assumption), Zeeman concentrates his defences on one of our minor criticisms, which concerns the direction of curl of the isolated neural plate. In rebuttal we note that it is Zeeman, not ourselves, who is misquoting Crelin, who clearly states that the graft curls

laterally (Crelin *J. Exp. Zool.* 120, 547; 1952 and private communication); that the mesoderm is too thin to exert the forces Zeeman ascribes to it; and that 'neurulation', the subject of the section containing Zeeman's statement, includes Harrison stage 23, which Crelin studied.

Returning to Prof Guckenheimer's letter: he disagrees with our definition of the word 'catastrophe'; but the definition we use is that used by all the applied catastrophe theorists that Guckenheimer is defending. We agree with Guckenheimer's statement that the confusion of the intuitive notion of jump with the mathematical notion of jump discontinuity is common and useful. What we object to are attempts to switch from one to the other and back in mid-proof. Finally, Guckenheimer complains that our remark about the large number of unrefereed applied catastrophe theory papers is "snide". First of all, it is a fact. Consider, for example, the bibliography prepared by the strong catastrophe-theory supporter Lynn Steen in February, 1977 (Steen: *Catastrophe Theory: A Selected Bibliography* (mimeographed, 1977)). Approximately 70% of the papers classified there as applied catastrophe theory appear to be unrefereed; we think that this is an unusually high ratio for scientific papers. While no one would say that it is wrong to publish an unrefereed paper, we think it is quite proper to point out this phenomenon, because it indicates that catastrophe theory has grown in an atmosphere largely sheltered from outside criticism, and this partly accounts for its exuberant claims.

RAPHAEL S. ZAHLER

New Haven, Connecticut

In support of boycotts

SIR,—Richard Peto and Sir Richard Doll raise an important and difficult issue in their letter about boycotts of congresses to be held in countries controlled by repressive regimes (1 December, page 384). As one who lived and worked in South Africa until government action forced me to leave, I can say something about this topic from 'the inside', as it was a subject often discussed by those of us who wished to see change and about which conflicting views were held. I emerged from these discussions as a strong proponent of boycotts for the following

reasons (most of which form answers to the points raised by Peto and Doll):

- It is often argued that boycotts cause harm to the people one least wishes to harm—opponents of the regime, scientists who need "contact with the international community" or, in the case of economic boycotts, the mass of people of the country (for example, the blacks of South Africa). The fallacy in that argument is that most genuine opponents of repressive regimes will already have been dealt with by the government—imprisoned, silenced by banning, or even murdered. In most countries scientists can, and do keep contact with the rest of the world by travel and are not restricted unless they are actively engaged in politics or openly express opposition to the regime; if they do, they are likely to be dealt with as above. And, in my experience, a majority of politically-aware blacks in South Africa would have accepted the damage that might have resulted from economic sanctions as a necessary and effective means of putting pressure on the government.

- Visits to these countries by prominent people or holding of international congresses is often regarded as tacit acceptance of the regime by the rulers and sometimes exploited as evidence of its acceptability. To opponents of the regime such actions bring a sense of disillusionment and cynicism, and I recall the moral encouragement and gratification one felt whenever a prominent artist, scientist or sportsman announced publicly that he would not visit South Africa.

- Peto and Doll imply that scientists should be "apolitical" as this confers on them a special "useful image", presumably to be used for protests, such as that made by so many scientists against the imprisonment of Mikhail Shtern. The argument may be used with equal force by doctors, sportsmen, artists, businessmen or any other person pursuing any other occupation! No group is immune from the responsibility to take a political stance at times, whether this is expressed as a letter of protest or a boycott.

- Boycotts are often said to be ineffective and therefore not worth supporting. This is only true when they are not fully supported. The sporting isolation of South Africa has been most effective and has led to removal of many of the barriers imposed in that country against mixed-

race sporting activities.

● Would-be visitors to these countries often say they go to see and hear things for themselves. Indeed, I have often been asked to provide introductions to black opponents of South Africa's regime who could provide visitors with their side of the story. I reply that most genuine opponents have already been silenced one way or another and I would certainly not put at risk those who had escaped the net of repression by encouraging them to speak out to inquisitive strangers. I have known many doctors and scientists who have visited South Africa in the past ten years; most return to this country with new arguments and convictions, if not fully in favour of apartheid, at least condoning or "understanding" it, now that they've "seen the problem" for themselves (or been indoctrinated by their proselytising hosts?). Some come back encouraged by a few whispered sentiments of distaste for the regime, mistakenly to believe that there still exists in that country a substantial courageous body of doctors or scientists who oppose apartheid and are doing something actively about it. Not one of my colleagues has met a black person socially, and none has spoken out against the regime while he was there ("How could I say anything when they were my hosts?").

Clearly, one could carry such convictions to absurd lengths. Some degree of repression exists in most countries; minority groups often appear to be singled out and treated badly. Where one draws the line is a matter for individual decision. What I'm saying is simply that if one feels strongly enough about a situation in a particular country, there are good arguments in favour of staying away—and of making one's reasons known.

The University of Birmingham, UK

Sauce béarnaise

SIR,—Perram, Nicolau and Perram recently described a method for reversing what they called coagulation of *sauce béarnaise* by addition of extra vinegar (*Nature* 270, 572–573; 1977). They stated that other authors recommend discontinuation of the 'experiment' of producing *sauce béarnaise* when coagulation occurs.

Amateur, non-mathematical cooks, such as myself, know that two kinds of deviation from homogeneity can occur during the preparation of *sauce béarnaise* and similar sauces such as *sauce hollandaise* (see Elizabeth David's book, *Summer Cooking*, first published by Penguin in 1955). The colloidal suspension can separate into its components, no doubt due to the forces

described by Perram *et al.* I have found, however, that sauce which has failed in this way can be made homogeneous quite simply by the addition of a few drops of warm water with steady stirring. This has the advantage of maintaining the delicate flavour balance, which would be disturbed by the unnecessary addition of extra vinegar. The second deviation from homogeneity occurs when the temperature of the sauce rises too high: the egg yolk becomes coagulated—as Elizabeth David notes—and the sauce becomes grainy in texture. This process cannot be reversed by the addition of acetic acid and it is to this event which culinary authors are referring when they recommend discontinuation of the 'experiment'.

ROY JOHNSON

Cambridge, UK

SIR,—We welcomed the long overdue treatise by Perram *et al.* on the stability of the colloidal suspension colloquially known as *sauce béarnaise*. However, as the authors claim primacy in reporting their successful attempt to resurrect this sauce by employing the theory of the stability of lyophobic colloids, we feel compelled to mention a previous notation in this field—Child, J., Bertholle, L. & Beck, S. *Mastering the Art of French Cooking* (Knopf, New York, 1966). The use of *lemon juice* here substitutes for acetic acid.

G. STEARNS

R. WEININGER

New Haven, Connecticut

SIR,—A professional biologist (and amateur cook) is amazed that Perram, Nicolau and Perram could by consideration of the theory of stability of lyophobic colloids deduce that lumpy *sauce béarnaise* could be made smooth by the addition of acetic acid and confirm it in practice. The biologist would not call the lumpiness coagulation, which to him is an irreversible reaction (Chambers Dictionary of Science and Technology) though the chemist may. The biologist would also control his experiment by addition of acetic acid solution without the acetic acid, i.e. water. This, reducing ionic strength, the practical cook has done with equal success for decades, though this 'know-how' is seldom described in manuals of gastronomy.

Furthermore, the first step in preparation of *sauce béarnaise* is a drastic 'reduction' by heat. Does not this remove most, if not all, of the original volatile acetic acid molecules before the addition of the fats? If so, the charge on the fat droplets must be provided not by acetic acid molecules, as postulated, but by less volatile acids

of the herbs and vinegar—impurities to the chemist but quintessential factors to the gourmet and variable damn-nuisances to the cook.

Harwell, UK

SIR,—Perram *et al.* are to be congratulated on their attempt to define the underlying physico-chemical principles of the unstable system known as *sauce béarnaise*, and in particular on their published observation that addition of vinegar (acetic acid) will resurrect the sauce.

However, I must point out that my wife has adopted this practice for some years now on the very rare occasions when the sauce has coagulated. No doubt, other good cooks have done the same: cooks, however, unlike scientists, usually prefer to keep their knowhow secret rather than divulge it.

Calculating the fine structure constant

SIR,—I would like to cite two references *Physics Today*, 24, 8, 17 (1971) and 24, 11, 9 (1971), in which reports have been published of attempts to calculate empirically the fine structure constant, whose experimental value in physics is 137.03602.

In these papers, the authors have attempted to calculate the value of the constant with pure members and π . The results are all very complex, and none are in exact agreement with the experiment.

I would like to propose a much simpler solution whose value is in exact agreement with the experiment.

$$137.0360157 = [137^2 + \pi^2]^{1/2}$$

Since this expression is very simple, it must be the true solution.

THOMAS J. BURGER

Bright minds not wasted

SIR,—Your editorial (24 November, page 287) on the dearth of scientific appointments was immodest, probably unintentionally. "How do we get ourselves out of this bind, ensuring that bright minds are not wasted?", is the sentence that offends. I for one do not feel that my students will be necessarily accepting second-best if they do not become professional scientists.

The tenor of the article was antagonistic to the idea of the best minds going into other fields. Is it not this attitude which has made it necessary to force such a change for the good of the larger community?

Chemical waves in *Drosophila*

from Jonathan Slack

OTHER sciences may progress by conjecture and refutation but this can hardly be said of contemporary developmental biology. Here progress occurs by the successive formulation of models whose quality is judged, at least in the first instance, by the amount of applause from the audience when they are first unveiled.

1978 has started well with a new model from S. Kauffman, R. Shymko and K. Trabert with what amounts to a general theory of development in the fruit fly *Drosophila melanogaster* (*Science* **199**, 259; 1978). The new model does nothing less than account for the relative positions of different parts of the organism and the assignment of the correct intrinsic characteristics of each part.

To understand what this means we must remember that most of the adult fly is formed during metamorphosis from groups of cells called imaginal disks. The rudiments of these disks are laid down in early embryonic development and during the life of the larva they grow but do not visibly differentiate. It has recently been shown that during their growth the disks become subdivided into compartments (Garcia-Bellido, Ripoll & Morata *Devl Biol.* **48**, 132; 1976). These compartments have the property that once the boundary has formed, the cells from the neighbouring compartments can never cross it, so each develops by further subdivision but not by recruitment of cells from outside. Certain homeotic mutations result in the partial or total conversion of one compartment within a disk into another. For example, the mutant *engrailed* converts the posterior compartment of each of the thoracic structures (wing, legs, haltere) into the anterior compartment. (Lawrence & Morata *Devl Biol.* **50**, 321; 1976). It is now widely believed that the compartment boundaries are the thresholds between the on and off states of the wild type alleles of what Garcia-Bellido calls selector genes; in which occur the homeotic mutations.

J. Slack is a developmental biologist working at the ICRF Laboratories, Mill Hill, London.

Another property of the imaginal disks is that they can be cultured in the abdomens of adult flies for long periods of time and then forced to differentiate by implantation into a larva about to undergo metamorphosis. In general their state of determination (leg, wing, genital, and so on) is conserved during culture, but occasionally a so-called transdetermination occurs whereby a certain type of disk changes to another state of determination. Several of these changes are also mimicked *in vivo* by homeotic mutations.

Kauffman has previously published a most persuasive analysis of this and related data from which he concluded that the states of determination of the disks are given by a combinatorial 'epigenetic code' of 'on' and 'off' states of the selector genes (*Science* **181**, 310; 1973). A mutant selector gene will behave as though it were off in any combination and so may change several disks or compartments to different states of determination.

So, the development of the adult fly involves first the regionalisation of the embryo into a number of territories which will become the various disks and perhaps also the larval segments, and second a subdivision of each of the disks into its compartments. We wish to know how these subdivisions can be carried out to yield the correct combinations of selector gene activity in each compartment, and how the positions of the compartment boundaries, or thresholds of gene activity, are determined. The new model proposes an answer to these questions and it does so by bringing a new actor onto the stage to join the gradients and thresholds which usually play out the drama on their own.

Dissipative structures

This is the dissipative structure, the theory of which has been developed over the past 30 years by the able team of physical chemists in Brussels (see *Self Organisation in Non-equilibrium Systems*, Nicolis G. & Prigogine I., 1977). A spatial dissipative structure is a stable pattern of chemical concentrations distributed in space.

Such phenomena are called 'dissipative' because they can only arise in systems which are maintained far from thermodynamic equilibrium by a continuous flux of matter through the network of reactions.

This situation may seldom be encountered in the test tube but is of course the norm for biochemical reactions in the living cell. Dissipative structures are possible for coupled pairs of reactions which have particular relations of auto and cross catalysis, and although most of the work on their properties has been theoretical, several of the predicted dynamical features are realised in the Belousov-Zhabotinskii reaction (Winfree *Science* **175**, 634; 1972).

Drosophila model

As far as the *Drosophila* model is concerned the essential feature of this type of reaction network is that many dissipative structures may be possible for the same system. As a controlling parameter is varied the system will pass through a predictable sequence of spatial patterns. The conditions for the transitions can be established by the mathematical techniques of bifurcation theory which can indicate the critical parameter values at which the homogeneous state ceases to be stable to thermal noise, and which particular patterns present in the thermal noise will be selected for amplification.

Consider a straightforward example where the reactions are proceeding in a tube of length L . If L is small enough only the homogeneous state will be stable. Now imagine that the length is gradually increased. Above a critical value L_1 , the homogeneous state will cease to be stable and will be replaced by a monotonic gradient. At a greater length L_2 , the homogeneous state will be re-established. At L_3 , a second pattern mode will appear, which is a distribution of concentration of \wedge or \vee form. At L_4 , the second mode will revert to homogeneity. At L_5 , a third mode will arise, of the form \sim , and so on. In the general case there may not be a unique final outcome for a given length, but in the *Drosophila*

model there is a separate interval of length for each successive mode and the rather deep mathematical problem of predicting intermode transitions is avoided.

Suppose now that the reactions are proceeding not in a tube but in a growing line of cells. The cells contain switches which will turn on the selector genes when the concentration of the dissipative structure reagent exceeds a certain value. We have to assume that a different switch becomes responsive each time a new pattern mode is established. We further assume that the threshold values for all the switches are near the nodal values of the patterns, that is the concentrations which are the same as those of the homogeneous steady states. So when the first mode is set up with a single node in the centre, the first selector gene is turned on in one half of the line of cells and off in the other half. When the second mode is established there are two nodes which bisect the two regions defined by the first switch. If the first modes are of the respective form \backslash and \cup , then the states of gene activity from left to right will be 11, 10, 00, 01. As each new mode appears, its switch will bisect previous regions in such a way that each new compartment is defined by a unique combination of states of gene activity.

This is the essence of the *Drosophila* model. The patterns are more complicated because they are formed not in a line of cells but on various two-dimensional domains: a growing ellipse

represents the growing imaginal disks and an ellipsoidal surface represents the early embryo. It is shown that the nodal lines which appear on an expanding ellipse are very similar to the arrangement of observed compartment boundaries on the fate map of an imaginal disk. The early embryo does not grow in size, but here a fall in diffusion constants due to cellularisation could have an analogous role. It is proposed that five sets of boundaries arise and divide the embryo into 32 regions. The binary coding of the selector genes in these regions corresponds very closely to that predicted from relative transdetermination frequencies, and to the occurrence of certain homeotic mutations.

Is it correct?

If the model were even approximately correct, it would certainly go down in history as a great scientific advance. Its beauty derives from the diverse strands of thinking which come together in the one great synthesis: gradients, thresholds, a binary combinatorial epigenetic code, dissipative structures.

But is it right? In its favour are several impressive retrodictions of known facts. For example, it is known that the anteroposterior subdivision of the embryo commences before the dorsoventral. So the model can lay down both axes of the body with the one mechanism, and the sequence arises naturally from the fact that the long axis of an ellipsoid is longer than

the short axis. Another striking example is the mutant *antennapedia* which converts the antenna into the second leg. The model explains that it must be the second leg rather than the first or third because of their different specific codings.

There are also several known facts which seem unfavourable for the model at the moment. It would be churlish to run through a long catalogue of counter arguments, but one group of phenomena is so strongly at variance that it cannot be ignored. This is the evidence for some sort of monotonic gradient which controls pattern formation in the early embryo. The evidence for a single (or double) controlling gradient is discussed in detail by Sander (*Adv. Insect Physiol.* **12**, 152; 1976) and rests largely on the results of constriction experiments on the eggs of a variety of insect species. There is also evidence for the existence of a persistent monotonic gradient in the imaginal disks which enables fragments to regenerate, sometimes across the compartment boundaries (Bryant *Curr. Top. Devl Biol.* **8**, 41; 1974). The observed behaviours in these experiments are hard to explain by the new model. It should also be borne in mind that the evidence for gradients exists in many developmental systems which have been carefully examined (sea urchin, *Hydra*, and the vertebrate limb for example) while the evidence for binary decisions and a combinatorial code, persuasive as it is, is confined to the insects alone. \square

Replication origins

from David Sherratt

A REPLICON is a contiguous segment of DNA constituting a unit of replication. By definition a replicon controls its own replication; determination of the rate of DNA initiation from a unique origin is generally accepted as the point of control. Most information about origins, initiation and subsequent movement of the replication fork has been furnished by simple viral and plasmid replicons. However, because these depend on their hosts for most of the DNA replication machinery, it should be possible to extrapolate to the more complex host chromosomes.

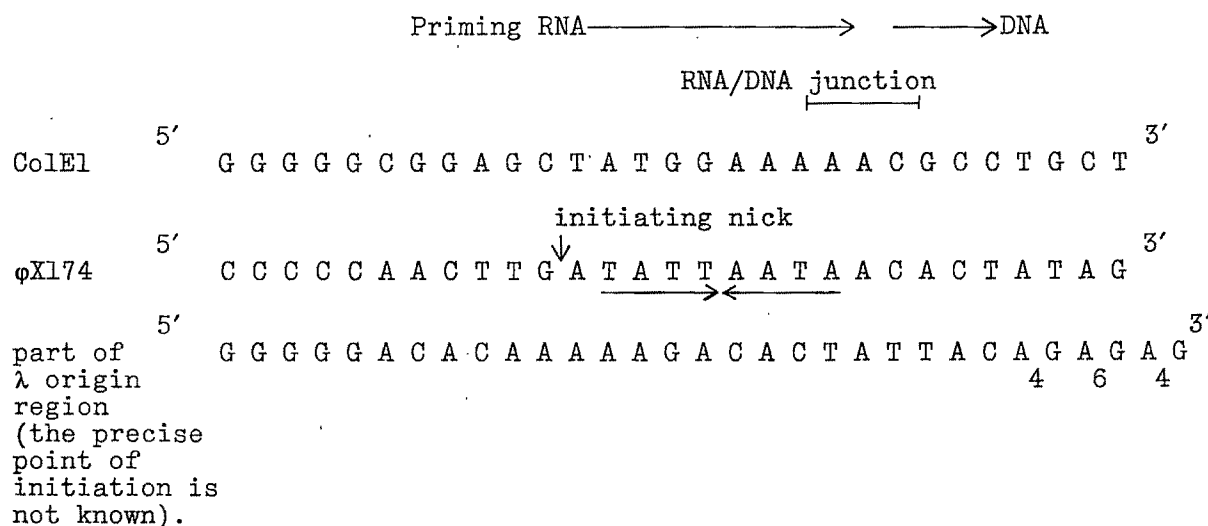

DNA polymerases, unlike RNA polymerases, are unable to initiate polynucleotide chains *de novo*, probably because of the high probability of introducing irrevocable error by mispolymerisation on a short chain, which by

its nature is poorly base-paired to the template strand. Two ways of overcoming this dilemma are known. The most widespread is to utilise RNA 'primers' to provide a base-paired 3'OH group to which deoxyribonucleotides can be added. Since this RNA is 'non-genetic' and is later removed, errors in its polymerisation can be tolerated. Unidirectional or bidirectional replication can follow equally well from such RNA priming. In principle, this type of initiation could be controlled either at the level of initiation of RNA synthesis or at RNA termination/DNA initiation.

Another apparently less common way of initiating DNA replication is to create a deoxyribonucleotide 3'OH primer by nicking a parental DNA strand internally. Replication from such a nick can most simply generate a unidirectional 'rolling circle' and occurs in the replication of the double-stranded DNA bacteriophage ϕ X174.

The new DNA sequencing technology has already been used to determine the sequences at or near both types of origin, including those of phages ϕ X174 and λ , plasmid ColEI and the eukaryotic viruses SV40 and polyoma. F. Blattner's group in Madison has isolated and sequenced a functional λ origin (*Science* **198**, 1041; 1977). Their sequence contains a number of long pyrimidine tracts (one of 18 nucleotides), many runs of greater than four identical nucleotides and a number of direct, inverted and palindromic repeats that allow hairpin loops to be constructed. Unfortunately the functional significance of these features remains obscure, as does the nature of the initiation of λ replication. ColEI vegetative replication is initiated from a RNA primer and Tomizawa and coworkers (*Proc. natn. Acad. Sci. U.S.A.* **74**, 1865; 1977) have sequenced the region about the RNA/DNA junction, which is A-T rich and is preceded one to two helix

David Sherratt is a lecturer in the School of Biological Sciences, University of Sussex.

turns before by a G-C rich region. Such a structure is reminiscent of known RNA termination sequences (*Nature* 271, 275; 1978). The same sort of distribution of A-T and G-C rich regions can also be seen in λ and ϕ X174.

In Utrecht, Langeveld *et al.* (page 417 in this issue of *Nature*) have sequenced the region on the 3'OH side of the specific nick in duplex ϕ X174 DNA at which replication is initiated. This nick is introduced by the *cis*-acting ϕ X174 A protein. Reassuringly, this sequence is present in the ϕ X174 total sequence (*Nature* 265, 687; 1977). Adjacent to the nick is a rotationally symmetrical octanucleotide which could be a specific (A-protein?) protein-binding site.

Initiation is likely to be controlled by replicon-specific 'signals' that allow or prevent replication. ϕ X174 and λ each produce initiator proteins (A and O respectively) and it is perhaps not surprising that the genes for these proteins overlap the respective origins of replication. The *E. coli* chromosomal origin is also close to the *dnaA* gene which is involved in replication initiation. In contrast, since ColEI is able to initiate replication in the absence of ColEI-specified proteins, its initiation may be controlled by a repressor.

The ϕ X174 A protein appears to be the prototype of a range of important enzymes which nick DNA but conserve the phosphodiester bond energy by becoming covalently bound to the 5' end of the nicked strand (possibly through a phosphoamide bond, as in the ligase-AMP complex); they are subsequently able to religate the 5' end to the original or possibly a new 3'OH with little or no further energy input. With ϕ X174 this allows a simple mechanism for the production of single strand circular viral strands by a modified 'rolling circle' model (Eisenberg *et al. Proc. natn. Acad. Sci. U.S.A.* 74, 3198; 1977). By analogy, a simple mechanism for conjugal transfer of plasmid DNA and its recircularisation

in the recipient presents itself. Not surprisingly then, ColEI 'relaxation complex', which has similar properties to the ϕ X174 A protein/DNA complex, seems to be involved in conjugal transfer rather than vegetative replication, since work in our laboratory has shown that deletion of the specific site of ColEI relaxation complex nicking abolishes conjugal transfer without noticeably affecting vegetative replication. It would seem that this site is a transfer origin. An SV40 'relaxation complex' that can be nicked close to the origin has also been described (Kasamatsu & Wu *Proc. natn. Acad. Sci. U.S.A.* 73, 1945; 1976).

DNA nicking-closing enzymes also belong to this class. A particularly interesting example is *E. coli* DNA gyrase, which *in vivo* introduces negative superhelical turns into covalently closed DNA. Nalidixic acid, a potent inhibitor

of DNA replication has recently been shown to interact with DNA gyrase. *In vitro*, gyrase can introduce negative superhelicity (in the presence of ATP), remove superhelical turns, and in the presence of nalidixic acid and SDS can cleave seemingly specific phosphodiester bonds, becoming covalently bound to the 5' end of the breaks in the process (Sugino *et al. Proc. natn. Acad. Sci. U.S.A.* 74, 4767; 1977; Gellert *et al. Proc. natn. Acad. Sci. U.S.A.* 74, 4772; 1977). Since introduction or removal of superhelical turns needs continuous nicking-closing activity, the conservation of phosphodiester bond energy is clearly important. DNA gyrase has been clearly implicated in DNA replication, yet its *in vitro* properties also make it, or similar 'break-rejoin' enzymes, candidates for involvement in recombination and transposition. \square

A new type of chemisorptive bond

from R. H. Williams

DURING the past few years there has been great progress in our understanding of atomically clean solid surfaces and of the nature of chemisorption on them. This has been mainly due to the combination of new surface sensitive electron spectroscopic and other techniques (see Woodruff *Phys. Bull.* 27, 165; 1976) with sophisticated theoretical calculations of the surface on an atomic level. These studies are important in understanding processes such as catalysis, corrosion or the behaviour of many electronic devices.

Silicon has been particularly thoroughly studied in this respect because of its great technological importance and the availability of ma-

terial of high perfection. Clean (111), (110) or (100) silicon surfaces contain bonds which are not attached to other atoms, the so called 'dangling bonds'. For the (111) surface there is just one dangling bond per surface atom, extending out normal to the surface. Adsorbed gases such as chlorine bind to this bond, as illustrated in the beautiful recent angularly resolved photoelectron spectroscopic experiments of Larsen, Smith and Farrell (*Proc. V Int. Conf. Vacuum Ultraviolet Rad. Phys. Montpellier*, Extended Abstracts, II, 241; 1977).

On the theoretical front calculations of the surface electronic and vibrational structure have been made by several groups. In particular Appelbaum and Hamann at Bell Telephone Laboratories have conducted a series of

R. H. Williams is Reader in Physics at the New University of Ulster.

calculations in which the charge and potential are treated self consistently (see *CRC Crit. Rev. Solid State Sci.*, August, 357; 1976) for a number of plausible clean surface structures and ones covered by adsorbed atoms. Although low energy electron diffraction gives the symmetry of the surface unit mesh the exact positions of the surface atoms are not known precisely. Figure 1a shows the form of the (100) surface, the atoms labelled 1 being the topmost layer, 2, 3, and so on being in subsequent layers. Atoms 1 have two unsaturated bonds. Obviously gases such as atomic hydrogen form strong covalent bonds with these unsaturated electrons. Since all the bonds associated with atom 2, in the second layer are saturated one would not expect hydrogen to form covalent bonds with these atoms.

In a recent paper, however, Appelbaum, Hamann and Tasso (*Phys. Rev. Lett.* **39**, 1487; 1977) conclude that if a hydrogen atom is located directly above atom 2 in Fig. 1 then it can form an unconventional type of covalent bond with the underlying silicon atom. As the hydrogen atom is brought to the surface immediately above atom 2 the charge distribution in the system as well as the force between the atoms is calculated as a function of separation d . It is shown that the hydrogen atoms have little effect on the dangling bond states. For $d = 3.7$ a.u. there is an attractive force between the hydrogen and silicon and as d decreases the attractive force also decreases until $d \sim 2$ a.u., with an accompanying polarisation of the charge around the silicon atoms in the second layer. It then increases rapidly until $d \sim 1$ a.u. and subsequently again decreases, reaching zero for $d \sim 0.25$ a.u. For values of d below 1 a.u. the behaviour of this force relationship is similar to that for hydrogen above a surface silicon atom. In addition the bond charge between the first and second layer silicon atoms is reduced by about 20%, weakening the bond and presumably allowing the bond distance to expand. In fact a simple interpretation of this unconventional covalent bond is that it is made up from valence-bond orbitals centred on the bond charge between the first and second layer Si atoms, and the hydrogen 1s state, somewhat analogous to the multicentred bonds formed in some boron compounds. The bonding combination leads to a tightly bound state, the anti-bonding combination yields a partially occupied state in the Si band gap, whilst the non-bonding combination weakens the Si-Si bonds. In addition the polarisation surface state noted for large d drops to an energy ~ 1.5 eV lower than for the conventionally bonded hydrogen on Si (111). It seems very likely that this

Fig. 1 a, Top view of silicon (100) surface; b, side view of same surface. The uppermost atoms, labelled 1, possess two unsaturated bonds. The hatched circle represents hydrogen.

state has been detected experimentally in the photoemission experiment of Sakurai and Hagstrum (*J. Vac. Sci. Tech.* **13**, 807; 1976) when hydrogen was adsorbed on Si (100) at room temperature.

Undoubtedly there will be further experimental and theoretical investigations of this new type of chemisorptive

bond for hydrogen on silicon and for other systems. It is of interest to note that such bonds may be of importance in amorphous silicon films prepared from silane by the R.F. glow discharge method and first prepared in n and p type form by Spear and LeComber (*Phil. Mag.* **33**, 935; 1976) at the University of Dundee. This material incorporates hydrogen in the lattice and promises to be of considerable use for manufacturing cheap solar cells. □

A new generation of elementary particles

from F. E. Close

EACH year the British high energy physics community meets at the Rutherford Laboratory to review the status of the field. In the past 3 years the discoveries of charm and the unification of two of the natural forces (electromagnetism and the weak force of radioactivity) have been highlights of the meetings. This year's meeting was perhaps even more exciting as discoveries in the past few months have heralded the opening of a new chapter in our conception of the microworld.

Three generations of elementary particles

Our everyday world can be loosely thought of as built from a hydrogen atom template (an electron and proton system) with neutrons (forming nuclear isotopes) and the radioactive phenomenon where a neutron transmutes into the proton with emission of an electron and also a ghostly neutrino (ν_e). The electron and neutrino are a pair of elementary particles called leptons. The proton and neutron on the other hand are now believed to be clusters of elementary particles called quarks. The quarks in the proton and neutron are of two varieties (or flavours), 'up' (u) and 'down' (d). Particles like the proton are made up of three quarks—two ups and one down for the proton itself—whereas

the other class of particles called mesons, that act as the carriers of the strong force between protons and neutrons, contain a quark and an antiquark. The best known meson is the pion (π) which is a combination of an up and a down quark but there are many other mesons, such as the heavier ρ meson and the much-disputed A_1 meson.

This pair of up and down quarks has many properties in common with the lepton pair and there appears to be a deep connection between them. These lepton and quark pairs are today known as the 'first generation' of elementary fermions.

For a reason not yet understood Nature repeated itself. The muon (seemingly a heavy version of the electron (see *News and Views* **266**, 679; 1977)) was discovered over a quarter of a century ago. It too is partnered by a neutrino and hence there is a 'second generation' of leptons (μ , ν_μ). We now know that there is also a second generation of quarks. The strange particles contain a strange (s) quark. The discovery of the J/ψ in 1974 was the first evidence for a charmed quark (c). In 1976 it was found that the c and s quarks are indeed brothers, dramatically in accord with theoretical predictions (*Nature* **262**, 537; 1976).

Charm, the sensation of the past 3 years, took a back seat this year. Interesting discoveries were reported which

F. E. Close is at the Rutherford Laboratory

further support the charm hypothesis (see also *News and Views* 269, 286; 1977) and these are adding greatly to our understanding of quark dynamics. While much exciting work still lies ahead, charm is now 'in the textbooks', and the discovery of the decade was overshadowed this year by the astonishing discovery that Nature seems to employ a 'third generation' of elementary particles.

A new heavy lepton — τ

For 2 years there have been signs that a new heavy lepton τ exists. Although the consensus of opinion supported this view there was always some doubt as to whether the signals that were being attributed to the τ (whose mass was around 1,800–1,900 MeV) were really arising from decays of the lightest charmed particles (1,865 MeV).

A very important result seems to be emerging from DORIS, the e^-e^+ colliding beam facility at Hamburg. Since the lightest charmed particle is at 1,865 MeV then 3,730 MeV of energy is needed to produce pairs of charmed particles. Hence the particle ψ' (3,684 MeV) cannot decay into pairs of charmed particles and yet the signals that seem to characterise the production of pairs of the hypothetical τ lepton are being seen in decays of ψ' (3,684). Hence the signals are genuinely from τ , and not charm. Moreover the mass of τ is now believed to be within 20 MeV of 1,810 MeV, some 50 MeV lighter than the lowest charm mass.

Decay properties have been studied and are in line with what would be expected if the τ is accompanied by a new neutrino ν_τ (analogous to the ν_e and ν_μ , first and second generations). There is however a tantalising puzzle: the τ is seen to produce the ρ in its decays in accord with calculation; also the A_1 is seen (confirmation of the A_1 is an interesting 'old' physics by-product of this new world); however, no sign of the π is seen. This should be produced in $\tau \rightarrow \pi + \nu_\tau$. One suggestion put forward is that the ν_τ has spin 3/2 (unlike spin 1/2 for ν_e , ν_μ). If so, a whole new ball game lies ahead.

Another possibility is that the experimentalists should look harder.

A fifth quark?

If there is a third generation of leptons, theorists have argued that there should be a third generation of quarks. This new quark pair is labelled t and b for 'top' and 'bottom'.

In the summer of 1977 a massive Y (upsilon) particle (mass 9.4 GeV—three times that of the ψ , and nine times heavier than the proton) was seen in muon pairs produced by proton–proton collisions at Fermilab. It is now confirmed that there is also an Y' some 600 MeV heavier than Y . This is tantalisingly the same mass differences as in $\psi' - \psi$ and so theorists speculate that these Y are bound states of a new quark (bottom seems to fit

better with the production rates than does top), and that the quarks feel a potential that rises logarithmically with the inter-quark separation (since this leads to splittings in mass for $\psi'\psi$ or $Y'Y$ independent of the mass scale).

Confirmation of the Y world has come from the intersecting storage ring at CERN where an enhanced production of lepton pairs is seen in the 9–10 GeV region—their resolution cannot separate Y and Y' however.

Bottomless particles?

The ψ had hidden charm—formed by a charmed quark and a charmed antiquark binding together producing a particle with net charm zero—and particles with naked charm were subsequently found. Hence, if the Y has 'hidden bottom' (made from bottom quark and its antiquark) then one predicts that 'naked bottom' particles will exist. Similarly if top quarks exist then 'naked top'—or 'topless' states will eventually be found. The prudish may care to note that t and b are said to stand for truth and beauty, rather than top and bottom, by some physicists. It is predicted that these will decay in a cascade as follows: top decays weakly to bottom, bottom to charm and charm to strange. At each stage a lepton can be emitted. Hence one might anticipate that when a neutrino interacts with a proton several leptons may be produced, for example

A beautiful event with four energetic muons was reported at CERN last month. It is still too soon to say whether this is the first clue in the search for topless and bottomless particles or whether it is a manifestation of something 'conventional' like charm.

Where now?

The phenomenology of bottom quarks was described by J. Ellis (CERN). In particular he drew attention to work of Kobayashi and Maskawa in Japan (in 1972) which showed that the mysterious phenomenon of CP violation emerges rather naturally in a world with six quarks. If the third generation of quarks is indeed filled by subsequent discovery of the top quark then this phenomenon may at last be understood. The search for 'top' is now on.

H. Fritsch (CERN) led a discussion of the impact of the new discoveries on attempts to build gauge field theories unifying weak, electromagnetic and strong interactions. The latter part of this idea is exploitation of the theory of quantum chromodynamics (QCD) which has been developed over the past few years as a quantum field theory of strong interactions which describes the interactions

between quarks. G. Parisi (Ecole Normale, Paris) described some of the phenomena that QCD predicts should be seen in highly inelastic lepton scattering on protons and nuclei. T. Quirk (University of Oxford) showed data from such experiments which appear to be in accord with QCD predictions.

H. Lipkin (Weizmann Institute, Israel) described some exotic multi-quark states that should exist even with the first generation of quarks (see *News and Views* 266, 201; 1977) and discussed evidence for 'exotic nuclei' (dibaryon resonances) that may fit in with these ideas.

The evidence that Nature exploits gauge theories has led to an upsurge of interest in them and E. Corrigan (University of Durham) described some of the rich and exciting structure that is emerging from these studies. Theorists are preparing themselves for the possibility that we are now *en route* for a grand synthesis of all natural forces, including gravity. G. Gibbons (University of Cambridge) described recent work in quantum gravity. Physicists already punch drunk with new quarks, new leptons, monopoles and merons, were now introduced to gravitational monopoles, nut and bolt solutions and even had to contemplate a foam of black holes. When all of these incredible discoveries are finally welded together a profound conception of Nature seems likely to emerge that will make Star Wars seem child's play. □

Homo or hetero?

from Robert W. Cahn

At first sight, an ordered metallic solid solution is as simple and perfect as a crystal can be. Solvent atoms sit on one kind of lattice site, solute atoms on another. The supposed simplicity and perfection are deceptive, for any ordered alloy differs from a plain inter-metallic compound in that its ordered structure is unstable and dissipates on heating before the solid melts. The interest of such alloys does not lie in the perfection of the order, but in the mysterious intermediate states in which order begins to disappear; the halfway house between perfect crystallographic order and an utterly random distribution of atoms on the available lattice site. Are the wrongly sited atoms scattered at random among the 'right' ones—is there a randomness within the randomness—or are there minute groups of 'wrong' atoms, right with respect to their immediate neighbours but wrong with respect to the main mass of the ordered crystal? The first is a homo-

Robert W. Cahn is Professor of Materials Science at the University of Sussex.

geneous model of partial order, the second, a heterogeneous one. The homo/hetero dispute goes deep in this field of solid state physics.

When an ordered alloy is heated above its critical temperature, all long-range order disappears, but local or short-range order persists. Its persistence may be deduced from the observation of diffuse X-ray scattering in place of sharp superlattice lines, or from small thermal, electrical or dilatometric anomalies. The atomic format of short-range order is subject to the same uncertainty between homogeneous or heterogeneous models. One view is that a short-range-ordered alloy is homogeneous in the sense that any solvent atom has statistically the same likelihood of having like or unlike nearest neighbours as any other solvent atom. Of the several heterogeneous models, the most intriguing postulates a dispersion of tiny fully ordered domains surrounded by a wholly random matrix with a thin boundary in which there is a gradient of the degree of order. In other words, ordered 'precipitates' exist in a disordered matrix. This model, associated with H. P. Aubauer, has occasioned a great deal of controversy since it was first advanced 6 years ago. The difficulty is this: in the normal way, any dispersion of precipitates in a matrix is unstable; the Matthew Principle operates and large precipitates grow at the expense of the small. The same happens with soap bubbles or with raindrops in a cloud. Aubauer (*Acta Met.* 20, 165, 173; 1972) pointed out that a short-range-ordered, heterogeneous alloy remains indefinitely in a state of fine dispersion: the ordered microdomains do not grow however long they are heated. Aubauer attributes this to the presence of an elastic strain gradient around each domain (because the volume per atom is different in ordered and random regions), and the elastic energy is shown to inhibit the coarsening of domains. Aubauer's calculations have repeatedly been challenged on thermodynamic grounds (the story of the dispute is neatly anatomised by J. W. Martin and R. D. Doherty on pages 205-209 of their book, *Stability of Microstructure in Metallic Systems* (Cambridge University Press, 1976).

The homogeneous/heterogeneous dichotomy with regard to short-range order seems to be incapable of final resolution by X-ray diffraction, electron diffraction, electron microscopy or electrical resistivity. Copper-rich, alpha-phase Cu/Al solid solutions in particular have been examined by all these techniques, over a period of 20 years, and though the partisans of heterogeneity have the edge, the arguments have been impossible to resolve decisively.

A deceptively simple investigation has now, to all appearances, tilted the balance firmly in favour of a heterogeneous model (although that still leaves open the question whether Aubauer's particular version is the most apposite). L. Trieb and G. Veith (*Acta Met.* 26, 185; 1978), two Viennese physicists working in consultation with Aubauer, have studied several Cu/Al alloys exclusively by measurements of electrical resistivity. In the past (for instance in a classic study by Wechsler and Kernohan, *Acta Met.* 7, 599; 1959) this has been done by quenching from high temperatures, which leads to great complexities arising from quenched-in vacancy populations which lead to kinetic anomalies. Trieb and Veith avoided large temperature changes: an ultraprecise measurement technique allowed them to cool or heat their samples by only 5 °C, so that in effect the only variable to affect the resistivity was a change in degree of short-range order. By approaching the same end-state from above and below, they were able to define the temperature range in which equilibrium was attainable in reasonable times in their various alloys. They then analysed mathematically the form of the kinetic curves and showed unambiguously that these could only be interpreted on the hypothesis that two different processes were in progress at different rates. Twin-process kinetics cannot be reconciled with a homogeneous end-structure. Trieb and Veith point out that in Aubauer's 'disperse order' model, an alloy of given composition has at each temperature, in equilibrium, a defined volume fraction of ordered domains and a defined mean size of domains. They propose that the equilibrium volume fraction is attained several times faster than is the equilibrium degree of dispersion, following any sudden small change of temperature. The electrical resistivity is sensitive to both variables and can thus be used to follow their changes. For the most concentrated alloy (18 at. % Cu) the disordered matrix virtually disappears and is replaced by antiphase boundaries.

Trieb and Veith have made a very convincing case for the correctness of a heterogeneous model and have shown how powerful a basically very simple technique, allied with extreme precision and careful quantitative analysis, can be.

It is intriguing that the homo/hetero dispute extends also to the structure of oxide glasses. An enormous amount of work has gone into analysis of such glasses by diffuse X-ray scattering, but it is fair to say that the resultant pair-distribution functions cannot reliably discriminate between homogeneous (Zachariasen-type) network models and various models based on non-crystalline

clusters, or clusters of microcrystals of two polymorphic variants in co-existence. This battleground of glass structures still awaits its resolution, which will perhaps come, in due course, from some technique as elegant and simple as that applied by Trieb and Veith to short-range order.

Their study has shown again the limitations of microscopy, however great the resolution and however sophisticated the technique, in resolving details of not-quite-perfect structures. □

Negative deflection angles in heavy ion scattering

from P. E. Hodgson

WHEN two nuclei interact at energies high enough to overcome their mutual electrostatic repulsion their quantum-mechanical wavelengths are usually small compared with their own radii, so that it is possible for many purposes to consider them as classical particles moving along well-defined orbits. If we then think of the scattering angle as a function of the impact parameter we find several curious effects, in particular that several impact parameters can give the same scattering angle. It has now proved possible to distinguish these orbits experimentally.

The orbits can be visualised by considering the interaction for various impact parameters, or distances of closest approach in the absence of all interactions. For large impact parameters the projectile feels only the long-range repulsive Coulomb (or electrostatic) field and is deflected through a small positive angle. As the impact parameter is decreased the nuclei come closer together so the Coulomb interaction is larger and the repulsion and thus the deflection angle is greater. Thus initially the deflection angle increases as the impact parameter decreases.

As the impact parameter is still further decreased the nuclei approach close enough for their short-range attractive nuclear fields to interact. These oppose the repulsive Coulomb force and thus reduce the scattering angle. Eventually as the impact parameter is reduced still further there comes a point when the Coulomb and nuclear fields exactly balance and the particle is not scattered at all. At still smaller impact parameters the scattering angle becomes negative, and the corresponding orbits wind round the

P. E. Hodgson is a lecturer in Nuclear Physics at the University of Oxford.

back of the target nucleus as shown in the inset to the figure.

Although there is a clear physical difference between the orbits corresponding to positive, and negative scattering angles, they cannot be distinguished experimentally just by studying the differential cross sections, since equal number of particles are incident on both sides of the target nuclei. Thus until recently it was not possible to confirm these negative deflection angles experimentally, although they are theoretically very plausible.

It has now been shown by Trautmann and colleagues (*Phys. Rev. Lett.* 39, 1062; 1977) that it is possible to do this by measuring the polarisation of the residual nuclei, which depends on whether the scattering was to positive or negative angles. This is because in these interactions some of the orbital angular momentum of the projectile is given to the target nucleus, so that it is left spinning. If now we consider two orbits that both give emergent particles in the same direction, but one corresponding to positive and the other to negative scattering angle, we find that they leave the residual nucleus spinning in opposite directions, as shown in the inset to the figure. This may easily be seen physically by using the concept of tangential friction; the interactions that take place as the nuclei brush past each other transfer energy and this is felt by the projectile as a tangential force tending to set it into rotation; the same force also sets the target nucleus into rotation.

The particles that have traversed the two types of orbit can be distinguished by the amount of energy they have lost in the interaction. Those scattered through positive deflection angles have been strongly repelled by the Coulomb field and weakly attracted by the nuclear field. Since the loss of energy and the transfer of particles takes place mainly through the nuclear field, such particles will on the average lose rather little energy. On the other hand those particles that are scattered through negative deflection angles have been acted on by a relatively weak Coulomb field but a very strong nuclear field, and so will have lost on the average much more energy. This is illustrated by the figure, which shows the energy spectrum of the particles emitted at 35° from the interaction of 284 and 303 MeV, argon nuclei with a target of natural silver. There are two distinct peaks, the one at higher energies corresponding to the particles that have lost rather little energy in quasi-elastic interactions, and the one at lower energies that have lost much more energy in deep inelastic inter-

The upper half of this figure shows the coincident energy spectra of emerging particles with charges between 11 and 21 from the interaction of 284 and 303 MeV argon nuclei with natural silver. The deep inelastic and quasi-elastic groups are clearly distinguished. The lower part of the figure shows the corresponding polarisations, and the inset shows how these follow from the classical orbit picture of the interaction.

actions.

It is possible therefore to identify the particles that have been scattered through positive and negative deflection angles so all that remains is to show that they have indeed left the residual nuclei spinning in opposite directions. This was done by measuring the circular polarisation of the de-excitation gamma rays corresponding to the two groups. In the initial stages of the de-excitation process charged and neutral particles are emitted, and this will in general reduce the value but not change the sign of the nuclear polarisation. Thus the circular polarisation of the gamma rays emitted in the last stages of the de-excitation process, which has the same sign as the nuclear polarisation, tells us about the direction of spin of the residual nucleus immediately after the interaction.

The results of the measurements of the circular polarisations of the gamma rays in coincidence with the two groups of particles are shown in the figure. Those corresponding to the negative deflection angles have a small positive polarisation, whereas those corresponding to positive deflection angles have a small negative polarisation, which is just what we expect from the theory of the process. This agreement with the theory of the orbits responsible for the positive and negative scattering angles and the energy losses of the particles in the two groups confirms the overall correctness of the picture. This is a remarkable illustration of the value of

classical arguments in understanding the details of interactions between nuclei at high energies. □

What's special about enzymes?

from G. C. K. Roberts

A Ciba Foundation Symposium on Molecular Interactions and Activity in Proteins was held at the Ciba Foundation on 6-7 December 1977. It was organised by Professor A. R. Battersby, University of Cambridge. The Proceedings will be published by Elsevier/Excerpta Medica/North Holland.

THE symposium was devoted to a discussion of the special catalytic powers of enzymes, and the extent to which this can be explained in precise chemical terms. W. N. Lipscomb (Harvard University) began by summarising the ways in which the remarkable rate enhancements observed with enzymes might be achieved, emphasising that enzymes operate by normal chemical mechanisms, using specific binding to speed things up. He went on to describe model systems which illustrate some of the contributions to enzymic catalysis. Perhaps the most striking example was

the reaction which, due to the 'locked' conformation of compound I is 5×10^{10} times faster than the reaction of the corresponding compound without the methyl groups (Milstein & Cohen *J. Am. Chem. Soc.* 94, 9158; 1972).

It was clear from the examples shown that there are enough factors demonstrable in model systems to account for the power of enzyme catalysis. In which case, what about building a 'model enzyme'? The early stages of an attempt in this direction were reported by J. R. Knowles (Harvard University), who described the design and synthesis of a modified cyclodextrin as a catalyst of phosphate ester hydrolysis. Aromatic molecules are known to bind in the central 'hole' of cyclodextrins, while the catalytic site was provided by three $-NH_3^+$ groups positioned so as to stabilise the transition state. Unfortunately, testing of this ingenious compound as a catalyst was not complete at the time of the meeting; however

G. C. K. Roberts is at the National Institute for Medical Research, Mill Hill, London.

specific binding was demonstrated and it promises to give considerable insight into the requirements for optimal catalysis. Another area in which the organic chemical approach has made enormous contributions to our understanding of enzymes is that of stereochemistry; D. Arigoni (ETH, Zurich) described an elegant series of studies of biological methylation reactions using S-adenosyl methionine labelled with a chiral methyl group (—CHDT).

F. M. Richards (Yale University) described computations of the solvent-accessible surface area of proteins; contrary to earlier generalisations, the surface of a protein is made up of polar and non-polar groups in roughly equal proportions. Richards showed that calculations of changes in surface area can be used to estimate 'hydrophobic' interactions, and that they could form the basis of a program which searched for optimal helix-helix contacts, and which worked well for myoglobin—an encouraging step towards an algorithm for protein folding. He also pointed out that calculations of the packing density of atoms in a protein lead to a 'solid-like' picture of the interior of a protein. This raised the question of flexibility in proteins which was taken up by a number of other speakers throughout the meeting. D. M. Blow (Imperial College, London) discussed crystallographic evidence for large scale flexibility in some proteins, particularly Huber's work on trypsinogen and his own on tyrosyl tRNA synthetase, in which about a third of the subunit fails to give rise to any interpretable electron density. K. Wüthrich (ETH, Zürich) and R. J. P. Williams (University of Oxford) drew attention to NMR evidence for mobility in proteins, principally at the level of single residues. It seems clear that proteins in general are more flexible than the 'solid-like' description implies, although the degree of flexibility varies substantially, not only from one protein to another but within one protein—as exemplified by pancreatic trypsin inhibitor. As pointed out by Wüthrich, this protein is both rigid, in that several peptide NH protons fail to exchange with the solvent on a timescale of years, and flexible, in that the aromatic rings of its tyrosine residues are able to 'flip' through 180° at rates of the order of 10^3 s^{-1} . The possibility that flexibility is in some way essential to catalysis was discussed both by Williams and also by B. Vallee (Harvard University) in describing his studies of arsanilazo-tyrosine 248 carboxypeptidase. Optical absorption, circular dichroism and resonance Raman spectroscopy were used to obtain structural information on the environment of the 'probe', which

could then be related to individual kinetic steps in catalysis.

Turning to substrate binding, C-I. Brändén (Uppsala) described crystallographic work on liver alcohol dehydrogenase, including studies of a ternary complex, enzyme.NAD⁺.p-bromobenzyl alcohol. In this enzyme, the substrate binds at the bottom of a very deep pocket, lined exclusively with hydrophobic residues, where it coordinates to the zinc atom—the only specific enzyme-substrate interaction that is apparent, thus explaining the very broad specificity of the enzyme. Brändén reported that it is very difficult to say from the crystal structures why substrates bind 2–3 orders of magnitude more tightly in the presence of coenzyme; a subtle change in the electronic structure of the zinc may be involved. H. Gutfreund (University of Bristol) described transient-state kinetic studies of the alcohol dehydrogenase reaction, presenting evidence for proton release accompanying the binding of NAD⁺. This proton may well originate from a 'charge relay' system, comprising Asp 293–His 151–Ser 48—(water or alcohol)—zinc, at the active site. An interesting, though as yet unexplained, generalisation noted by Brändén is that in almost all enzymes having a parallel β -sheet structure, the C-terminal part of the sheet contains an anion binding site; in dehydrogenases the pyrophosphate of the coenzyme binds here, in carboxypeptidase the carboxylate of the substrate, and in rhodanese a thiocyanate ion.

Several other speakers took up the question of the specificity of binding in a pharmacological context; G. C. K. Roberts (National Institute for Medical Research, London) discussed the origins of the very tight binding of inhibitors to dihydrofolate reductase, emphasising the role of conformational changes, while M. Halsey (Clinical Research Centre, London) described studies of the binding of general anaesthetics to haemoglobin. T. Blundell (Birkbeck College, London) showed how the combination of the crystal structure with studies of modified insulins makes it possible to define those regions of the molecule which most probably interact with the receptor.

The reactivities and pK_a values of side chains on enzymes can be markedly altered from those of the free amino acids, and this can make a significant contribution to the observed rate enhancement. D. C. Phillips (University of Oxford) and Williams described a combined onslaught, by crystallography and NMR, on lysozyme, asking whether one could predict the reactivity of pK_a of a side chain from its environment as revealed by crystallography. While the exchange rate of the indole NH protons of the

tryptophan residues, for example, correlated well with their solvent accessibility, this was not the case for iodination of the tyrosine residues—the most readily iodinated tyrosine was neither the most solvent accessible nor the one with the most 'normal' pK_a .

Perhaps the most remarkable example of a special environment for a side chain of an enzyme was described by B-M. Sjöberg (Stockholm). Ribonucleotide reductase contains a stable free radical, which is most probably involved in the activity of the enzyme, and which is formed on the side chain of a tyrosine residue, the spin density being located on carbons 1, 3 and 5 of the aromatic ring. The stability of such a radical during purification and handling of the protein is really quite extraordinary.

In his summary, Lipscomb noted that, though we are fairly sure we understand the general principles governing the behaviour of enzymes, we do not know exactly how things work in any individual case. This clearly applies not only to catalytic activity but also to the details of specificity and reactivity. The fact that precise chemical questions can be asked about such systems, if not yet answered, is a mark of the progress that has been made, but theoretical advances will be required before we can properly relate structure and energetics. □

A hundred years ago

ON Monday afternoon a powerful shock of earthquake was felt in the island of Jersey. It was so strong as to cause houses to totter and bells to ring. Its course was from east to west. There was at the time a heavy gale from the south-west in the English Channel. At 11.55 A.M. the same day a shock, lasting about four seconds, was felt at Eastern Alderney. No doubt it was the same earthquake which was felt at Brighton, Blackheath, Fareham, and St. Leonards, as reported in yesterday's *Times*, and at Paris, Havre, and Rouen, as stated by the *Times* Paris correspondent. Mr. Dobson, writing to us from the Royal Victoria Hospital, Netley, Southampton, states that the first shock occurred there at seven minutes to twelve o'clock exactly, and lasted about five or six seconds. It was sufficiently strong to cause the door to shake with some violence, and many objects in the room continued to vibrate for a considerable time.

review article

Quantification of Earthquakes

Hiroo Kanamori*

Because earthquakes are the result of complex geophysical processes, it is not a simple matter to find a single measure of the size of an earthquake. Further, extremely large earthquakes saturate the conventional magnitude scale. Recent estimates of energy released by such earthquakes suggest values high enough to have possible implications for plate motion, the Chandler wobble and rotation of the Earth.

DURING 1976 a large number of destructive earthquakes occurred: on 4 February, Guatemala suffered an earthquake of magnitude 7.5, with the loss of 23,000 lives; on 6 May, an earthquake of magnitude 6.5 cost Italy 1,000 lives; on 27 July, an earthquake of magnitude 8.0 struck China with the loss of 650,000 lives. The Chinese (Tangshan) earthquake is one of the most disastrous events since the 1556 Chinese earthquake in which 830,000 people perished. Moreover, there have been several other destructive earthquakes in the same year: Fig. 1 clearly demonstrates that 1976 was one of the worst years for earthquake casualties in recent times. However, the damage caused by an earthquake depends not only on its physical size but also on various factors such as when and where it occurs, and Fig. 1 therefore does not necessarily represent the physical 'size' of earthquakes. The question of how we measure the 'size' of an earthquake has been historically a very important yet difficult seismological problem.

Earthquake magnitude scales and seismic energy

Since the physical process underlying an earthquake is very complex, we cannot express every detail of an earthquake by a single parameter. However, it would be convenient if we could find a single number that represents the overall physical size of an earthquake. This was the very concept of the earthquake magnitude scale, the so-called Richter scale, introduced by Charles F. Richter¹ in 1935. Richter used the maximum amplitude of seismic waves recorded by the Wood-Anderson seismograph. After correcting for the decay of the amplitude with distance from the epicenter, he established the local magnitude scale (M_L) for earthquakes in Southern California, using the logarithm of the observed amplitude of seismic waves. The seismic waves used for local magnitude have periods ranging approximately from 0.1 to 2 s, equivalent to a wavelength of 300 m to 6 km. Since Richter's scale was introduced more or less empirically, it was not quite clear in the beginning what physical parameter of an earthquake this scale represented. However, the Richter scale turned out to be extremely useful for various purposes. The method was so simple that magnitudes could be assigned to hundreds of earthquakes on a routine basis. Since M_L is defined in the period range where the effect of seismic waves on buildings is most pronounced, it is a very good measure of the strength of ground shaking at a given distance, and is very useful for various engineering purposes.

Because of this remarkable success of the M_L scale, Gutenberg² extended this kind of measure to earthquakes in distant sites.

For earthquakes at very large distances, seismic surface waves with a period around 20 s are often dominant on seismograms. Gutenberg therefore defined another magnitude scale, M_S , called the surface-wave magnitude, using the amplitude of surface waves with a period of 20 s. The wavelength of these surface waves is about 60 km. Gutenberg³ also used seismic body waves (P and S waves) to define another scale, m_b , called the body wave magnitude. The period of these body waves is usually from 1 to 10 s. Thus M_S and m_b represent different parts of the frequency spectrum of seismic waves, so that each of these scales represents a different physical parameter of an earthquake. However, extensive studies of Gutenberg and Richter suggested that m_b and M_S seem to be related to each other and could be used to represent a fundamental physical parameter, the energy of seismic waves, E . Through repeated revisions, Gutenberg and Richter⁴ finally derived a relation $\log_{10} E = 1.5 M_S + 11.8$ (E in ergs). This relation made it possible to estimate seismic energy from the magnitude M_S , which can easily be routinely measured. Of course, we cannot expect a very accurate estimate of seismic energy from such a crude parameter through such a simple relation. Nevertheless, this relation provided the only means for quantifying earthquakes in terms of the energy of elastic waves.

The monumental book of Gutenberg and Richter⁵, *Seismicity of the Earth*, catalogues most large earthquakes that occurred from 1904 to 1949. In the later work of Gutenberg⁶ and in the second edition of *Seismicity of the Earth* the catalogue was extended to the period from 1897 to 1952. Fortuitously, after these catalogues were completed, a number of very large earthquakes occurred starting with the Kamchatka earthquake,

Fig. 1 Loss of life caused by major earthquakes. The vertical bars are for the individual event and the solid curve shows the annual average (unlagged 5-year running average).

*Seismological Laboratory, California Institute of Technology, Pasadena, California 91125.

$M_s=8\frac{1}{4}$ on 4 November 1952. Here, 'large' refers to the length of the fault. The 1952 Kamchatka earthquake was followed by the Fox (Aleutian) Island earthquake in 1957, ($M_s=8\frac{1}{4}$), the Chilean earthquake in 1960 ($M_s=8.3$), the Kurile Island earthquake in 1963 ($M_s=8.1$), the Alaskan earthquake of 1964 ($M_s=8.4$) and the Rat Island earthquake of 1965 ($M_s=7\frac{1}{4}$). The faults which broke in these earthquakes are extremely long (as long as 800 to 1,000 km for the 1960 Chilean earthquake and the 1957 Fox Island earthquake). No faults that long are known to have ruptured for events before 1952, although the data before 1904 are incomplete. We will use the term 'great earthquakes' for these events with a very long fault.

Seismic waves generated by these great earthquakes are quite spectacular. Very long-period (200–300 s or even longer period) waves which last for several days after the earthquake are often recorded on long-period seismograms. However, the amplitude of relatively short-period (about 20 s) waves generated by these earthquakes is not particularly large, and is about the same as for 'ordinary' large earthquakes. Therefore M_s for these events is not particularly large, in spite of the extremely large fault length and the pronounced long-period waves. Since the energy was calculated only from M_s , the energy release of these 'great' earthquakes was thought to be comparable to that for other 'ordinary' large earthquakes. Why does the amplitude of short-period waves not grow as the length of the fault increases? The amplitude of seismic waves represents the energy released from a volume of crustal rock whose representative dimension is comparable to the wavelength. Several studies⁷ suggest that the energy density per unit volume of crustal rock is almost constant regardless of the size of the earthquake. Since the wavelength of seismic waves used for the determination of M_s is only about 60 km, the amplitude of 20-s waves does not increase as the fault length increases beyond 60 km; therefore the M_s scale saturates. Since these giant earthquakes occurred after the publication of *Seismicity of the Earth*, Gutenberg⁸ and Richter did not have the opportunity to consider the saturation problem.

Not much further effort was devoted to the question of energy estimation until the early 1960s, when remarkable progress was made in long-period seismology. Owing to the worldwide deployment of the standardised long-period seismographs and the development of the theory of the generation and propagation of very long-period (up to 1 h) waves, it became feasible to use very long-period waves for quantitative analyses of an earthquake source. Such long-period waves have wavelengths of several hundreds to several thousands of kilometers, which are comparable to the fault length of great earthquakes, and are therefore suitable for measuring the overall 'size' of great earthquakes.

Seismic moment

One of the major breakthroughs in this field was made by the introduction of the concept of seismic moment. Aki⁸ applied elastic dislocation theory to the study of earthquake mechanism. According to elastic dislocation theory, the amplitude of very long-period waves is proportional to the quantity $M_0=\mu DS$ where S is the surface area of the fault, D is the average displacement discontinuity on the fault plane and μ is the rigidity of the material surrounding the fault. M_0 is called the seismic moment. In order to obtain M_0 from the observed seismograms, the effect of propagation, attenuation and the geometry of the fault must be removed. Fortunately, unlike short-period (for example, 20-s) waves, these long-period waves are very coherent so that accurate measurements of M_0 are possible. Thus the seismic moment is one of the most reliable seismological parameters that represents the 'size' of an earthquake. Because M_0 does not saturate, it is a more suitable parameter to represent the size of great earthquakes than the conventional magnitude scales such as M_s .

Several attempts were made to use long-period (100–200 s) waves to quantify large earthquakes^{9–11}. Bruce and Engen¹⁰ introduced a new scale, 100 s magnitude M_{100} , which is based on the amplitude of surface waves with a period of 100 s instead of 20 s. This scale clearly demonstrated that long-period waves are very useful for distinguishing great earthquakes from ordinary large earthquakes.

In recent years, extensive efforts have been made to determine M_0 for great earthquakes as well as large and small earthquakes. The determination of M_0 for recent events can be made relatively easily and very accurately by using high-quality standardised seismograms. The determination of M_0 for old events is less accurate because of the poor quality of old seismograms. Nevertheless, by combining various techniques, the seismic moments of 44 earthquakes out of 52 events of $M_s \geq 8$ which occurred since 1921 have been estimated. For the period from 1904 to 1920, the data are not very complete. Fig. 2 shows the moments for the individual earthquakes as well as the annual average¹². Since the seismic moment directly represents the overall deformation at the earthquake source, Fig. 2 indicates the temporal variation of the amount of crustal deformation associated with earthquakes. It is clear that the seismic activity measured by the seismic moment was very high during the period from 1950 to 1965. The annual average seismic energy release during this period is almost two orders of magnitude larger than that during the period prior to 1950. Is this temporal variation real, or is it an artefact of the poor quality of the record for the period before 1950? Although the quality of the moment determination is somewhat poor before 1950, it is almost certain

Fig. 2 The seismic moment M_0 , seismic energy E , and the magnitude M_w of great and large earthquakes. The solid curve shows the annual average of seismic energy obtained by taking unlagged 5-year running average. A: Aleutian; Ak: Alaska; C: Chile; I: India; J: Japan; K: Kamchatka; Kr: Kurile; M: Mongolia; P: Peru.

Fig. 3 Comparison of *a*, the 1960 Chilean earthquake ($M_s = 8.3$) and *b*, the 1929 Aleutian Island (Fox Island) earthquake ($M_s = 8.1$) recorded by the Milne-Shaw seismograph. The long-period surface waves—marked as multiple surface waves—which are clearly recorded for the 1960 Chilean earthquake distinguish a great earthquake (Chilean earthquake) from a large earthquake (Fox Island earthquake).

that no earthquake from 1920 to 1950 was as large as the 1960 Chilean earthquake. As shown by Fig. 3, the difference between 'great' and 'large' earthquakes is quite obvious even on old seismograms. Thus, the pattern shown in Fig. 2 is probably real despite the differing quality of the data.

It is also clear in Fig. 2 that the annual average has decreased very dramatically in recent years. This trend is opposite to the trend shown in Fig. 1. This negative correlation clearly suggests that the physical size and the social impact of an earthquake are not directly related.

Seismic moment and seismic energy

The seismic moment can be related to the energy released in earthquakes. Suppose the stress on the fault plane is reduced from σ_0 to σ_1 in an earthquake. Then the reduction in the strain energy is $\Delta W = \sigma D S$ where $\sigma = (\sigma_0 + \sigma_1)/2$ is the average stress, D is the average offset on the fault plane, and S is the area of the fault plane. Combining this with the expression for the seismic moment M_0 we have $\Delta W = (\sigma/\mu)M_0$. If we assume that the fault motion stops when the stress on the fault becomes approximately equal to the frictional stress σ_f , that is $\sigma_1 = \sigma_f$, the above equation reduces to

$$\Delta W - \sigma_f D S = (\Delta\sigma/2\mu)M_0$$

where $\Delta\sigma$ is the stress drop $\sigma_0 - \sigma_1$. Since $\sigma_f D S$ is heat loss during faulting, the left-hand side of this equation gives the total strain energy minus heat loss. Therefore $(\Delta\sigma/2\mu)M_0$ can be considered as the energy available for generation of seismic waves. The stress drop $\Delta\sigma$ is known to be nearly constant for most great and large earthquakes (see for example ref. 13) and $(\Delta\sigma/2\mu)$ is approximately 2×10^{-4} . Therefore $M_0/(2 \times 10^4)$ gives an estimate of seismic energy E . Thus Fig. 2 can be considered as representing the temporal variation of seismic energy release. Note that the energy release in the 1960 Chilean earthquake is 10^{26} erg, which is about 60 times larger than the

value estimated from M_s .

Since the magnitude scale has been used for nearly 40 yr not only among seismologists but also by the news media, it is convenient to express the 'size' of an earthquake in terms of a magnitude scale. To this end, the energy $M_0/(2 \times 10^4)$ can be converted into a magnitude scale by using the energy-magnitude relation, $\log E = 1.5 M + 11.8$. A new magnitude scale, M_w is defined by¹²:

$$M_w = (\log M_0/1.5) - 10.7 \quad (M_0 \text{ in dyn cm})$$

In this scheme, the magnitude is defined in terms of the energy whereas in the old scheme, the energy is calculated from the magnitude. On this scale, $M_w = 9.5$ for the 1960 Chilean earthquake, 9.2 for the 1964 Alaskan earthquake, 9.1 for the 1957 Aleutian Island earthquake, and 9.0 for the 1952 Kamchatka earthquake. In Fig. 2, the M_w scale is given on the right. Comparison of M_w with M_s or M_L shows that M_w agrees very well with M_s and M_L for earthquakes with a smaller fault dimension; thus the M_w scale is a convenient extension of the old magnitude scale to great earthquakes.

Fig. 4 shows the spatial distribution of large earthquakes for the period 1904 to 1976. The values of M_w are given in the bracket for the ten largest earthquakes. It is notable that most of these earthquakes occurred along the Circum-Pacific subduction zones. These ten earthquakes account for more than 90% of the total seismic energy released from 1904 to 1976.

Although this estimate of the energy release of great earthquakes is much larger than that estimated earlier from the magnitude scale, it is still relatively small compared with the average rate of heat flow from the Earth's interior, 7×10^{27} erg yr⁻¹. The average annual rate of the seismic energy release is 4.5×10^{24} erg yr⁻¹, which is about three orders of magnitude smaller than the heat flow. Even for the largest event, the 1960 Chilean earthquake, the seismic energy is 10^{26} erg, which is about 1.4% of annual heat flow. However, the total strain

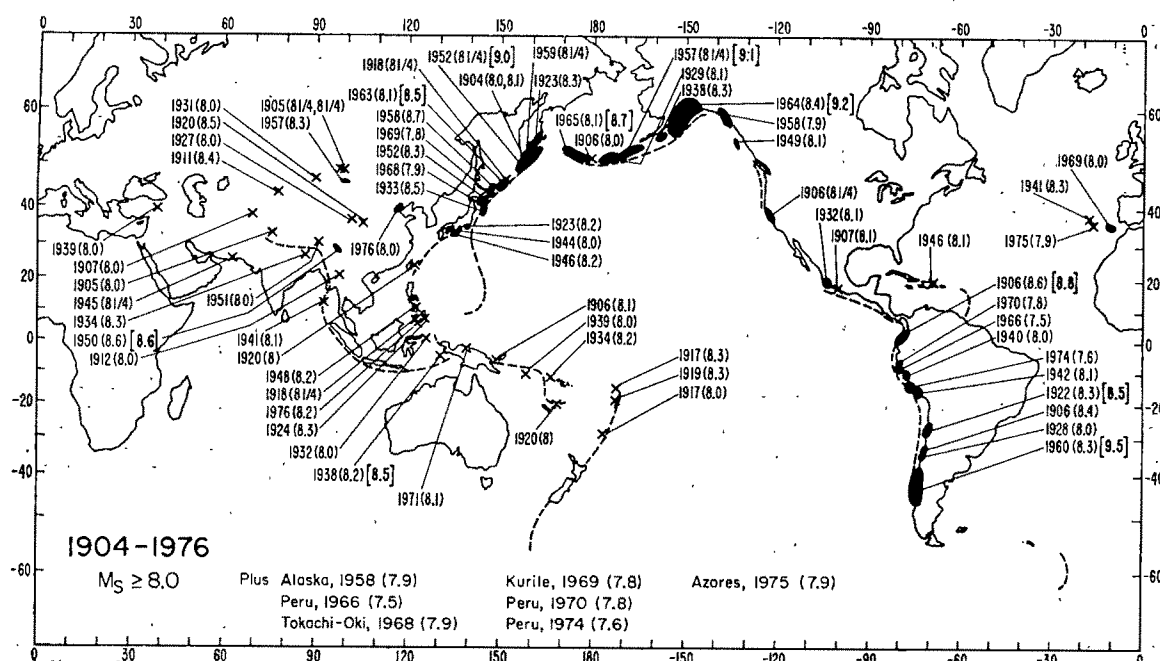

Fig. 4 Great and large earthquakes for the period from 1904 to 1976. The surface-wave magnitude M_s is given in the parentheses and M_w is given in the brackets for the ten largest earthquakes. Major rupture zones are indicated by dark zones.

energy change associated with an earthquake can be much larger (100 times more) than the seismic energy, if the stress drop in earthquakes is only a small fraction of the ambient tectonic stress. The discrepancy between the stress drop in earthquakes (10–100 bar) and the strength of rocks measured in the laboratory (several kilobar) suggests this possibility, but the problem remains unresolved up to now. If this is the case, the total energy involved in the earthquake process can be very significant in the energy budget of the Earth.

Since the total crustal deformation associated with great earthquakes is very large, the study of great earthquakes has a direct bearing on various global problems such as the Chandler wobble, plate motion and the rotation of the Earth^{14–16}. For the moment, the data and analysis are not complete enough to study this problem in detail, but with recent improvements in

instrumentation¹⁷ many important problems in this field may be resolved in the near future.

I thank Robert Geller and Seth Stein for helpful comments.

The alkaline earth hexammines have novel structures and molecular motions. The ammonia molecules in these compounds adopt an entirely different geometry from that of normal ammonia. There are two motional transitions as the temperature is increased. The first transition is due to ammonia rotation, and the second results from ammonia diffusion.

STRUCTURE and molecular motion in solids receive a great deal of experimental and theoretical attention and we have initiated a comprehensive research programme to investigate the compounds formed by reaction of elemental metals with ammonia. Only six metal-ammonia compounds are known: $\text{Li}(\text{NH}_3)_4$ and $\text{M}(\text{NH}_3)_6$, where $\text{M} = \text{Ca}, \text{Sr}, \text{Ba}, \text{Eu}, \text{or Yb}$ (ref. 1). All these compounds are metals, and their metallic nature originates from the loss of one, in $\text{Li}(\text{NH}_3)_4$, and two, in $\text{M}(\text{NH}_3)_6$, valence electrons from the elemental metal to a

*Onset temperature for the weak-narrowing transition.

†Onset temperature for the strong-narrowing transition.

conduction band. The motivation for our research is the belief—supported by electrical transport^{2–4}, magnetic^{5,6}, and magnetic resonance⁷ experiments—that these compounds are low-electron-density metals, and as such are rare model systems for testing theories of the electronic behaviour of solids at low electron densities. In addition to the unique electronic properties of metal-ammonia compounds, however, we have discovered that they exhibit both novel structures⁸ and molecular motions⁹. Here we report and interpret the results of our structural and motional studies on the alkaline earth hexammines $\text{M}(\text{NH}_3)_6$, where $\text{M} = \text{Ca}, \text{Sr}, \text{or Ba}$.

The structures of the deuterated compounds have been examined by powder neutron diffraction at 75 K (ref. 8). The sample-preparation technique and neutron spectrometer have been described elsewhere⁸. The hexammines all crystallise in a body-centred-cubic structure. The lattice constants are given in Table 1. To date, only $\text{Ca}(\text{ND}_3)_6$ has been examined in detail, and the atomic parameters were refined by a least-squares fitting of the diffraction profile. $\text{Ca}(\text{ND}_3)_6$ crystallises in the space group $\text{Im}\bar{3}\text{m}$ and has molecular complexes, $\text{Ca}(\text{ND}_3)_6$, located at each lattice site. The six nitrogens in a complex ion are arranged in an exact octahedron around the calcium, with a rather long Ca–N distance of 2.69 Å. The ammonia molecules in $\text{Ca}(\text{ND}_3)_6$ have an entirely different geometry from that of normal ammonia, where the N–H bond angle and distance are 110° and 1.00 Å, respectively. In $\text{Ca}(\text{ND}_3)_6$, the ammonia molecules are nearly planar and have two inequivalent sets of deuterons, with one N–D distance being short (0.94 Å), while the other two are extremely long (1.39 Å). Further evidence for this ammonia structure is provided by the low-temperature proton magnetic resonance (^1H NMR) experiments discussed below. Although each ammonia molecule is coordinated to the calcium by the nitrogen, the pseudotrigonal axis of each ammonia molecule is not coincident with the Ca–N bond, but makes an angle of 13° with it. Furthermore, each ammonia molecule has a 4-fold rotational disorder at 75 K, so that there are a total of 4⁶ possible ammonia orientations in each complex ion. One of the possible structures of the complex is shown in Fig. 1. In addition, there is no hydrogen bonding in the structure and virtually all nonbonded contacts are greater than the van der Waals distances, so that there are essentially no restrictions on the possible ammonia and complex rotations. The temperature factor is 7.4 Å², which indicates considerable thermal motion at 75 K. Although the structures of the other two hexammines have not yet been refined, we anticipate that the hexammines are isomorphous as their unit cells, lattice parameters, ^1H NMR, and chemical behaviour are nearly the same.

Molecular motions

Molecular motion in the alkaline earth hexammines has been investigated by ^1H NMR. The sample-preparation technique and wideline NMR spectrometer have been described elsewhere¹⁰. The spectra consist of a single asymmetrical line, as expected for metals having dimensions much larger than the skin depth, and the asymmetry parameters all lie in the range 1.4–1.9. The temperature dependence of the first-derivative peak-to-peak linewidth, ΔH , is shown in Fig. 2. In $\text{Sr}(\text{NH}_3)_6$, the signal was too weak to detect below 40 K. It is clear from Fig. 2 that all the hexammines exhibit the same qualitative behaviour. In particular, the low-temperature linewidth is about

2 G and, as the temperature is increased, there are two line-narrowing transitions. At the first transition there is a weak narrowing and at the second a very strong narrowing of the ^1H NMR line. The onset temperatures for these transitions are shown in Table 1. The strong-narrowing transitions are completed by 140 K. Above 140 K, the linewidth is independent of temperature and equal to 35 mG. But, because 35 mG is the magnetic-field inhomogeneity on our wide-line spectrometer, high-resolution ^1H NMR experiments were performed to determine the true linewidth. A Varian XL-100-12 NMR spectrometer, equipped with variable-temperature accessory, was used to record high-resolution ^1H NMR spectra in the range 190–300 K. A deuterium lock was employed by placing acetone- d_6 in the outer volume of a coaxial NMR tube (o.d. = 5 mm, i.d. = 3 mm). The measured full-width at half-maximum absorption is independent of temperature in the hexammines and equal to 15 mG. As the hexammines melt near 273 K, the linewidth does not change upon melting. Furthermore, the high-resolution linewidth in liquid ammonia just above the melting point is 11 mG, which is only 4 mG narrower than the hexamine linewidth above 140 K. Below we interpret the ^1H NMR linewidth results in the hexammines in terms of structure and molecular motion.

Linewidth results in hexammines

Using the interproton distances derived from neutron diffraction, the calculated rigid-lattice peak-to-peak linewidth is about 6 G (ref. 11), which is in poor agreement with the low-temperature linewidth of about 2 G. But if, by analogy to solid ammonia¹², the ammonia molecules in the hexammines tunnel at low temperature, then the estimated linewidth is about 3 G (the low-temperature linewidth was estimated by assuming that the intra and inter-ammonia contributions to the second moment are reduced by factors of $\frac{1}{4}$ and $\frac{1}{2}$, respectively, as found for these contributions in solid ammonia at low temperatures¹²), which is in reasonable agreement with experiment. This result supports the neutron-diffraction structure of

Fig. 1 One of the 4⁶ possible structures of the molecular complex $\text{Ca}(\text{ND}_3)_6$ in metallic $\text{Ca}(\text{ND}_3)_6$. The central calcium is octahedrally coordinated to the nitrogens of the six surrounding ammonia molecules.

Fig. 2 Temperature dependence of the linewidth (a) and semi-logarithmic plot of linewidth versus reciprocal temperature (b) for the alkaline earth hexammines.

the hexammines as the calculated low-temperature linewidth, using the structural parameters for an ammonia molecule in solid ammonia¹³ and assuming tunnelling, is about 8 G which is a factor of 4 larger than the experimental value.

We attribute the weak-narrowing transition to a transition from quantum-mechanical tunnelling to classical rotation of ammonia molecules. A similar weak-narrowing transition has been observed in solid ammonia between 60 and 80 K, and it was shown to result from the aforementioned rotational transition¹². Further indication of this rotational transition below 77 K in metal-ammonia compounds comes from changes in the electrical resistivity of $\text{Li}(\text{NH}_3)_6$ (ref. 14) and the Mössbauer resonant absorption in $\text{Eu}(\text{NH}_3)_6$ (ref. 15) near 70 K. The decrease in T_w with increasing molecular weight is correlated with a corresponding increase in cell volume (see Table 1); this should lower the barrier to rotation.

The strong-narrowing transition is indicative of other types of proton motion in addition to that associated with ammonia rotation. From the high-resolution ^1H NMR results, it follows that above the strong-narrowing transition the protons diffuse rapidly on the ^1H NMR time scale. Assuming that proton diffusion is a thermally activated process, we used the Gutowsky-Pake equation to analyse the linewidth data for the strong-narrowing transition:

$$\ln \Delta H = E_a/RT + \ln \alpha \gamma (\Delta H_{\text{RL}})^2 / \pi^2 \nu_0$$

where E_a is the activation energy, α is a constant of the order of unity, ΔH_{RL} is the rigid-lattice linewidth, and ν_0 is the vibrational frequency of the jumping atom or molecule¹⁶. (This equation is valid provided that $(\Delta H_{\text{RL}})^2 \gg (\Delta H)^2 \gg (\Delta H_{\text{HT}})^2$, where ΔH_{HT} is the residual high-temperature line-

width. The above inequalities hold over most of the strong-narrowing transition.) The jump frequency is given by $\nu_1 = \nu_0 \exp(-E_a/RT)$, and the reciprocal of the jump frequency is the correlation time, τ_c (ref. 17). As shown in Fig. 1, the semi-logarithmic plot of ΔH against T^{-1} is linear. Taking $\alpha = 1$ and $\Delta H_{\text{RL}} = 6$ G, the calculated values of E_a and ν_0 are summarised in Table 1. Also $\tau_c = 3.5 \times 10^{-8}$ s when $\Delta H = 0.2$ G, and τ_c decreases exponentially with increasing temperature. The low values of E_a and τ_c are consistent with rapid proton diffusion above 140 K. Also, it is interesting that ν_0 is in order-of-magnitude agreement with that expected for the metal-ammonia symmetric-breathing vibration¹⁸.

Mechanisms of proton diffusion

We have considered the following mechanisms of proton diffusion as the most likely possibilities: (1) isotropic reorientation of $\text{M}(\text{NH}_3)_6$ complexes, (2) diffusion of $\text{M}(\text{NH}_3)_6$ complexes, (3) proton exchange alone, and (4) diffusion of NH_3 . We have calculated that mechanism (1) results in a linewidth of about 1 G (noting that the effect of isotropic reorientation is to concentrate the 18 protons of a complex at the metal site, the linewidth was calculated by summing over the four nearest shells of complex ions and then integrating to estimate the remaining contribution. Nearest-neighbour interactions account for 85% of linewidth), so that it could account for only a small fraction of the observed narrowing. Although mechanism (2) would further narrow the line, we consider this process unlikely in view of the large diameter and mass of the $\text{M}(\text{NH}_3)_6$ complex. As T_s and E_a decrease with increasing molecular weight (see Table 1), it supports the contention that mechanism (2) is unimportant. As virtually all nonbonded contacts are greater than the van der Waals distances, mechanism (3) cannot occur by a rotational mechanism. The only other possibility is for (3) to break the N-H bond. However, molecular-orbital calculations have indicated that the N-H bonds in the hexammines are comparable in strength to those in ammonia (INDO calculations indicate that an ammonia molecule in the hexammines is less stable than normal ammonia by about 5 kcal mol⁻¹) so, as in ammonia, proton exchange does not occur until ammonia diffusion sets in.

We conclude, therefore, that the strong-narrowing transition in the hexammines is due to mechanism (4). (Intermolecular proton exchange accompanies proton diffusion in ammonia. It has been estimated, however, that the correlation time for such proton exchange is greater than 10^{-4} s (ref. 19), which is several orders of magnitude larger than the experimental correlation times. Hence the rate of proton exchange is very slow compared to that of ammonia diffusion, so that the integrity of the ammonia molecule is maintained above the strong-narrowing transition.) The ^1H NMR results are all consistent with this. The structural basis for ammonia diffusion is provided by the rather long M-N distance and nonstoichiometry²⁰. The long M-N bond is probably weak and hence can be broken easily, which accounts for the low transition temperatures and activation energies, and nonstoichiometry, in the form of ammonia vacancies, provides available sites to which the ammonia molecules can jump. The strong-narrowing transition may reflect a melting of the ammonia sublattice far below the melting point of the metal, and we believe this would be the first example of molecular-sublattice melting in solid state science. We are investigating this possibility using pulsed-proton NMR and inelastic neutron scattering to elucidate further the details of the motional transitions in the alkaline earth hexammines.

Finally, we shall comment upon the activation energies in Table 1. The experimental activation energies include the M-H bond energy as well as the energy required to transport ammonia, so that they are an upper limit to the N-H bond energy. The decrease in activation energy with increasing molecular weight follows from the corresponding increase in cell volume, which

increases the void volume available for ammonia diffusion and hence lowers the activation energy for transport, and also the expected corresponding decrease in bond energies, which lowers the activation energy for bond breaking.

This work was supported by NSF grant DMR 75-09215 and the Energy Research and Development Administration. We are grateful to the Center for Solid State Science and the Computer Center at Arizona State University for their facilities.

Nucleotide sequence of the origin of replication in bacteriophage Φ X174 RF DNA

S. A. Langeveld*†, A. D. M. van Mansfeld†, P. D. Baas†‡, H. S. Jansz†‡, G. A. van Arkel*† & P. J. Weisbeek*†

*Department of Molecular Cell Biology, †Institute of Molecular Biology and ‡Laboratory of Physiological Chemistry, State University of Utrecht, Utrecht, The Netherlands.

The gene A protein of bacteriophage Φ X174 has been used in vitro to convert Φ X RFI DNA into the relaxed RFII form by nicking the viral strand. The nucleotide sequence at the 3' end of the nick has been determined as -- T G C T C C C C C A A C T T G_{OH}. This sequence gives the exact position of the origin of Φ X RF DNA replication.

THE replication of the bacteriophage Φ X174 RF DNA and the way in which the viral gene A is involved in this process has been studied in great detail both *in vivo* and *in vitro*. Results of many workers show that the Φ X174 RF DNA replication starts by nicking the viral strand of the parental RFI DNA which is then elongated from the 3'-OH end under simultaneous displacement of the 5' end, using the circular complementary strand as a template. Therefore the 3'-OH end of the nick is the origin of Φ X RF DNA replication. This rolling circle mode of DNA replication was originally proposed by Gilbert and Dressler¹. The synthesis of a new complementary strand on the displaced viral strand occurs in small DNA fragments and therefore has no unique initiation site^{2,3}.

The location of the origin of replication has been investigated extensively *in vivo*. Repair studies with heteroduplex DNA showed the origin to be within gene A (ref. 4). Using *rep*⁻ cells, the position of the nick in the viral strand of Φ X RFI could be located with high precision in the *Hae*III restriction fragment Z6_B, approximately 185 base pairs away from the Z6_A/Z6_B junction⁵. The termination site for Φ X DNA replication has also been placed in this region of the Φ X genome⁶⁻⁸.

The gene A product of the phage is an absolute requirement for the RF DNA replication *in vivo*⁹. In their studies of Φ X DNA replication in *rep*⁻ cells, Francke and Ray^{10,11} showed that part of the parental RFI molecules was nicked in the viral strand only if a functional gene A product is present. Furthermore the gene A product was shown to be *cis*-acting, that is, in simultaneous infections with phage with an intact gene A and phage with a mutated gene A, only the RF derived from the phage with an intact gene A acquired a discontinuity in the viral strand. This is inconsistent with the asymmetrical

complementation behaviour of gene A mutants⁹. The gene A protein has been isolated since then¹²⁻¹⁴. It is a 55,000 molecular weight (MW) protein and it has a specific endonuclease activity. The A protein nicks Φ X RFI DNA once and in the viral strand only¹² and more precisely within gene A in the *Hind*II fragment R3 (ref. 14). These properties of the gene A protein clearly connect the 3' end of the nick made by the A protein with the 3' end that is the origin of RF DNA replication. The A protein fulfils all the requirements of the initiator protein in the replicon model proposed by Jacob, Brenner and Cuzin¹⁵. It is coded for by the viral replicon, it is required before DNA replication has started and it produces a free 3'-OH end that serves as a primer in the subsequent elongation of the viral strand.

We describe here experiments with the purified A protein and the determination of the nucleotide sequence at the 3' end of the nicked viral strand of RFI DNA that has been incubated with A protein. The sequence found identifies the site of the origin of replication unequivocally in the known nucleotide sequence of Φ X174 (ref. 16).

Gene A protein

THE A protein was isolated from *Escherichia coli* HF4704 (*uvrA*, *thy*, *sup*⁻) cells that had been infected with the lysis-defective phage mutant *am3*. The enzyme purification followed the procedure of Eisenberg *et al.*¹³ with the exception that no chloramphenicol was used during infection. This modification greatly improved the yield of the A protein. The enzyme preparation obtained after DNA-cellulose column chromatography (Fig. 1) contains the two proteins that are coded for by the gene A (ref. 17) (the 55,000 MW A protein and the 37,000 MW A* protein which has no nicking activity¹⁴). This protein mixture was used in the experiments on the endonucleolytic activity of the A protein.

The endonucleolytic activity of the A protein preparations was measured by the conversion of supercoiled covalently closed replicative form DNA (RFI) to the relaxed form containing at least one single-strand nick (RFII). This conversion was visualised on 0.6% agarose gels containing ethidium bromide¹⁸ by the difference in mobilities of the RFI and RFII

Fig. 1 Sodium dodecyl sulphate (SDS)-polyacrylamide gel electrophoresis of the A protein preparation. The A protein was purified from 15 g *E. coli* HF4704 infected with Φ X174 *am3* for 30 min, following the procedure of Eisenberg *et al.*¹³. Cells were lysed with lysozyme at 37 °C. Solid NaCl was added to a concentration of 1 M and cell debris was removed from the lysate by low speed centrifugation. Ammonium sulphate was added at 0.226 g per ml supernatant over a period of 20 min. After 15 min the precipitate was collected by centrifugation and resuspended in 50 mM imidazole-HCl, pH 6.7, 10 mM β -mercaptoethanol, 1 mM EDTA, 20% glycerol and 1 M NaCl and fractionated on a Biogel A 0.5 m column (150 ml) equilibrated in the same buffer. Proteins eluted from the Biogel column were applied to a Biorex 70 column (15 ml) in buffer containing 0.3 M NaCl. The column was washed with at least four column volumes and finally washed with buffer containing 1 M NaCl. The 1 M NaCl eluate was diluted to 0.4 M NaCl and passed through a single-stranded DNA-cellulose column (2 ml). The A protein was eluted from the column with 1 M NaCl. Each step in the purification was followed by electrophoretic analysis of samples on 12.5% polyacrylamide slab gels prepared according to Laemmli³⁶. *a*, The final A protein preparation after the DNA-cellulose column. *b*, The marker proteins are the phage proteins F, H, G and D with molecular weights of 48,000, 36,000, 22,000 and 14,500 respectively³⁷.

DNA molecules. The amount of RFI DNA converted to RFII DNA was dependent on the amount of A protein but never exceeded 50%. Whether this is the consequence of the presence of the A* protein or not, is unknown. No linear double-stranded DNA (RFIII) was formed, even after incubation with a 10-fold excess of A protein (compared with the minimal amount of A protein needed for 50% conversion). When incubation times were increased to 2 h, in some experiments a minor DNA band was formed that migrated with the mobility of RFI DNA containing no supertwists (relaxed RFI¹⁹). Relaxed RFI DNA formed during incubation of RFI DNA with A protein has also been found by Ikeda *et al.*¹⁴.

Incubation of the reaction mixture with proteinase K before phenol extraction is required for quantitative recovery of newly formed RFII DNA. The strong interaction of the A protein with the DNA causes the extraction of the DNA together with the protein out of the water phase.

The strand specificity of the enzyme activity was tested on RFI DNA labelled with ³H-thymidine in the complementary (—) strand only. Alkaline sucrose gradient analyses of the RFI DNA before and after incubation of this RFI DNA with the A

protein were carried out. The untreated RFI DNA (Fig. 2*a*) sediments much faster than single-stranded DNA. Figure 2*b* shows that after incubation of this RFI DNA with A protein almost all radioactivity in the RFII DNA formed is found after denaturation as circular single-stranded DNA. No increase in label is found at the position of linear single-stranded DNA. This indicates that the A protein nicks only the viral strand of RFI DNA (see also refs 12 and 14).

Site of cleavage

Attempts to label the 3' end of the nick made by the A protein in the viral strand of RFI DNA with terminal transferase²⁰ in the presence of Co²⁺ were unsuccessful. Also treatment of the RFII DNA with bacterial alkaline phosphatase followed by incubation of the DNA with T4 polynucleotide kinase²¹ did not result in incorporation of label at the 5' end. To circumvent the problems with intact RFII DNA, we determined first after digestion with the restriction enzyme *Hae*III in which restriction fragment the nick was located. This nicked fragment was purified and separated into its single-stranded components. The single-stranded viral (+) strand fragments were labelled at their 3' end and the nucleotide sequence at the site of the nick was determined. We were unable to label the 5' end of the nick.

³²P-labelled RFI DNA was digested with the A protein in conditions as described in Fig. 3. The mixture of RFI and RFII DNA was then digested to completion with restriction endonuclease *Hae*III. The digestion mixture was deproteinised by incubation with proteinase K followed by phenol extraction and the DNA fragments were separated on a 5% polyacrylamide slab gel. The separation of the fragments was visualised by autoradiography. The separate DNA bands were excised and the fragments eluted from the gel. All fragments were subsequently electrophoresed on slab gels in conditions in which all secondary structure of the DNA is disrupted²². The two strands of each restriction fragment are not separated in this gel system. Only the double-stranded fragment that contains the nick yields three single-stranded fragments of different size and mobility. This is shown in Fig. 3, the autoradiograph of the electrophoreses in denaturing conditions of the fragments Z6_B, Z7, Z8, Z9 and Z10. Z7, Z8, Z9 and Z10 give a single band but Z6_B is separated into three different fragments, approxi-

Fig. 2 Alkaline sucrose gradient analysis of RFI DNA treated with A protein. 1.25 μ g RFI ³H-labelled in the complementary strand (●) was incubated with 6 μ g A protein in 50 mM imidazole-HCl at pH 7.0, 60 mM NaCl, 10 mM MgCl₂ and 10 mM β -mercaptoethanol in a volume of 125 μ l at 37 °C for 30 min. Proteinase K (10 μ g), preincubated for 30 min at 37 °C, was added and the incubation was prolonged 20 min at 37 °C followed by extraction with phenol. The DNA samples were layered on 10–30% alkaline sucrose gradients (Baas *et al.*⁵) and centrifuged in the SW41 rotor for 24 h at 38,000 r.p.m. at 15 °C. ¹⁴C-labelled (○) single-stranded linear and circular DNA was added as markers. *a*, RFI DNA without A protein. *b*, RFI DNA after incubation with A protein.

Fig. 3 Autoradiograph of gel electrophoresis in denaturing conditions of the *Hae*III fragments Z_{6B}–Z₁₀. 400 µg RFI DNA was mixed with 50 µg ³²P-labelled RFI (4.6×10^8 c.p.m. Cerenkov) and incubated with 640 µg A protein in the conditions described in Fig. 2 legend. The final volume was 3.2 ml. The DNA was digested with *Hae*III followed by proteinase K treatment and phenol extraction. Fragments were separated on a 5% polyacrylamide gel that had been cross-linked with 0.3% ethylene-diacrylate in 50 mM Tris-borate, 1 mM EDTA pH 8.35, which was also the running buffer. Extraction of the DNA fragments was done by dissolving the gel in 0.5 M ammonium carbonate, 0.1 mM Mg acetate, 0.1% SDS and 100 mM EDTA at pH 9.2 for 16 h at 37 °C. Samples containing the fragments were diluted 20-fold with water and percolated through a hydroxyapatite column. Fragments were eluted with 0.4 M K phosphate, pH 6.8. The recovery was close to 100% for all fragments. The DNA fragments were alcohol-precipitated and dissolved in 20 µl formamide containing 20% sucrose, 0.1% xylene cyanol and 0.1% bromophenol blue and were incubated at 100 °C for 3 min. The longer fragments (Z₁–Z_{6A}) were layered on a 4% polyacrylamide gel made up in 98% formamide (not shown) and the shorter fragments (Z_{6B}–Z₁₀) on a 10% polyacrylamide gel made up in 98% formamide. The gels were made up as described by Maniatis *et al.*²². The length of the fragments in nucleotides is: Z_{6B} 278; Z₇ 234; Z₈ 194; Z₉ 118 and Z₁₀ 78 (ref. 16).

mately 280, 180 and 100 nucleotides in length. The 280 nucleotides band consists of the complementary strand and unnicked viral strand DNA of fragment Z_{6B}. Fragments Z₁ to Z_{6A} give only a single band (data not shown).

From this result we conclude that the nick introduced by the A protein in the viral strand of RFI DNA, is located in the *Hae*III fragment Z_{6B} and cleaves the viral strand of Z_{6B} in pieces of 180 (Z_{6B2}) and 100 (Z_{6B3}) nucleotides each.

The single-stranded fragments Z_{6B2} and Z_{6B3} were eluted from the gel and used for endgroup labelling. Incubation of fragment Z_{6B3} with terminal transferase and α-³²P-UTP in the presence of Co²⁺ in order to label the 3' end²⁰, resulted in incorporation of ³²P label (for details see Fig. 4 legend). The ³²P-labelled Z_{6B3} fragment was partially digested with micrococcal nuclease and spleen phosphodiesterase. The products were separated on the standard two-dimensional system²³ and after autoradiography the pattern presented in Fig. 4 was found. From the mobility shift of the labelled oligonucleotides^{24,25} the sequence of the 3' terminus was determined. The 3' terminal sequence of the fragment Z_{6B3} therefore is -T G C T C C C C C A A C T T G.

The last two nucleotides from the 3' terminus are not part of the *Hae*III recognition site (G G C C) and therefore this 3'

end must have been generated by the A protein. The fact that the 3' end has been extended by terminal transferase, which requires a free 3'-OH, indicates that the terminal G has a free 3'-OH group.

From these experiments we infer that the 5' end at the site of the nick is the same as the 5' end of the fragment Z_{6B2}. Experiments in which we tried to label this 5' end by treating Z_{6B2} with alkaline phosphatase followed by incubation with T4 polynucleotide kinase and γ-³²P-ATP were unsuccessful. This fact together with the observation that the A protein binds tightly to RFI DNA points towards an interaction of the A protein with the 5' end such that this end is no substrate for phosphatase and/or kinase. The presence of a 3'-OH group and a blocked 5' end at the nick has also been suggested by Ikeda *et al.*¹⁴.

Conclusions

The nucleotide sequence found at the 3' end of the endonucleolytic scission made by the gene A protein in the viral strand of RFI DNA has been determined. The nick is located in the *Hae*III fragment Z_{6B} within gene A²⁶. A comparison with the complete sequence of ΦX174 DNA¹⁶ shows that the sequence determined is unique in ΦX174 and corresponds to the nucleo-

Fig. 4 Autoradiograph of the two-dimensional separation of the oligonucleotides obtained after partial digestion of 3' labelled fragment Z_{6B3}. The DNA fragment Z_{6B3} was eluted from the gel shown in Fig. 3 and labelled with terminal transferase and [α-³²P]UTP in the presence of Co²⁺ by the method of Roychoudhury *et al.*²⁰. Then it was treated with alkali for 16 h at 37 °C, to remove all but the first transferred U residue. When this alkali treated material was incubated with alkaline phosphatase 50% of the ³²P label was removed from the DNA fragment indicating that at least two U residues had been added to each DNA molecule during the terminal transferase reaction. Analysis of a single-stranded DNA fragment with a known 3' end with terminal transferase showed that the terminal transferase was free of exonucleolytic activity. The alkali treated material was alcohol-precipitated, dissolved in 10 mM Tris-HCl pH 9.0, 2.5 mM CaCl₂ and incubated with micrococcal nuclease at 37 °C. After 15 min the pH was lowered to pH 5.0 with HCl and spleen phosphodiesterase was added. The required amounts of micrococcal nuclease and spleen phosphodiesterase and incubation times were determined in pilot experiments. The digestion products were separated in the standard two-dimensional system²³, using electrophoresis on cellulose acetate at pH 3.5 in the first direction and homochromatography on DEAE thin layer using a 3% homomix in the second direction. The oligonucleotides were visualised by autoradiography. Starting from the dinucleotide GU the nucleotide causing the shift of the next longer oligonucleotide is indicated.

Fig. 5 a, the 3' terminal sequence of Z6_{B3}, deduced from Fig. 4. b, the MRC sequence corresponding to the nick region¹⁶. The A protein cleavage site is indicated by the arrow.

tides 4,283 to 4,297 in the MRC sequence (Fig. 5). The sequence of the 5' end at the nick has not been determined. If we assume that no nucleotides are removed at the nick site, then the viral strand of RFI DNA is cleaved between the nucleotides 4,297 and 4,298. A free hydroxyl group is found at the 3' end thereby making the 3' end a primer for the subsequent elongation of the viral strand. The position of the nick is in full agreement with the *in vivo* origin of replication as determined by Baas *et al.*⁵. Also the C₆T-tract found by Eisenberg *et al.*⁸ near the origin is seen in our sequence 6 nucleotides away from the 3' end. This supports once again the assumption that the 3' end formed by the A protein functions indeed as primer in the synthesis of viral strand DNA and therefore represents the origin for the RF DNA replication.

The nick is located at the start of an A-T rich region (with the palindrome TATTAATA, underlined sequence in Fig. 5b) that is flanked on both sides by a G-C rich sequence (4,282–4,291 and 4,315–4,327 in the MRC sequence¹⁶). Origin regions of SV40²⁷, polyoma virus²⁸ and ColE1²⁹ have been also found to contain A-T rich sequences within G-C rich tracts. The size of and distance between these tracts, however, differ considerably from what is found at the ΦX174 origin. In the phages fd and G4 the region of the origin for the synthesis of the complementary strand on the infecting single-stranded viral DNA is known to contain considerable secondary structure^{30,31}. This is not seen in the ΦX174 origin region but it should be realised that the mechanism of initiation of the complementary strand DNA synthesis is different from the initiation of the viral strand DNA synthesis.

The A protein acts only on RFI DNA containing super-twists. Relaxed RFI is not cleaved³². Supertwisted DNA molecules are known to contain regions of partially single-stranded nature. These destabilised regions are rich in A-T³³. The A protein nicks the viral strand immediately next to an A-T rich sequence (Fig. 5).

If the enzyme needs a specific nucleotide sequence as well as a denatured region in order to nick then this might explain why only supertwisted ΦX174 RFI DNA and not relaxed RFI DNA is a good substrate. After nicking, the RFI DNA formed has a free 3'-OH end and a 5' end that after treatment with alkaline phosphatase cannot be used as a substrate for T4 polynucleotide kinase (neither for DNA polymerase I degradation¹⁴). This suggests a blocked 5' end. This fact together with the observed phenol-resistant binding of the A protein to the RF DNA indicates that the A protein remains attached to the 5' end. This suggests an additional function for the A protein during DNA replication. Covalent attachment of a protein to DNA has been observed with other viruses, for example, adenovirus³⁴ and SV40³⁵.

Synthesis and transport of the small subunit of chloroplast ribulose biphosphate carboxylase

Peter E. Highfield & R. John Ellis

Department of Biological Sciences, University of Warwick, Coventry, UK.

The small subunit of the chloroplast enzyme ribulose biphosphate carboxylase is synthesised as a precursor of higher molecular weight when poly A-mRNA from pea cytoplasmic polysomes is translated by wheat-germ ribosomes. This precursor is taken up into intact isolated chloroplasts, and cleaved to its final size in the absence of protein synthesis. It is deduced that the signal hypothesis does not apply to chloroplasts; an envelope carrier mechanism is proposed.

CHLOROPLASTS contain a distinct genetic system based on a double-helical DNA circle of average length 45 μm, and a 70S

ribosomal protein-synthesising machinery which accounts for up to 50% of the total ribosomal complement of photosynthetic cells¹. The total potential coding capacity of this circular DNA, assuming asymmetric transcription and allowing for an inverted repeat sequence², is about 6 × 10⁶ daltons of polypeptide. It is tempting to conclude that this genetic system synthesises most of the entire spectrum of chloroplast polypeptides, but the evidence does not support this conclusion. Inhibitor studies on intact cells suggest that many chloroplast polypeptides are synthesised by cytoplasmic ribosomes; examples are the Calvin cycle enzymes³ in the case of the stromal compartment, and the chlorophyll *a/b* binding protein^{4,5} in the case of the lamellar compartment. Genetic studies in both algae and higher plants have located the structural genes for several chloroplast poly-

peptides in the nuclear genome^{6,7}. It is thus clear that the formation of chloroplasts requires the integrated activities of both chloroplast and nuclear genomes. Current interest lies in defining the precise contribution of each genetic system and the mechanism of their interaction. Why do chloroplasts contain so many ribosomes, and how do those chloroplast polypeptides made by cytoplasmic ribosomes enter the developing organelle?

Recent technical advances have allowed the isolation of intact chloroplasts which use light energy to drive the synthesis of discrete protein and RNA molecules^{1,8,9}. Analysis of the products of protein synthesis in isolated pea chloroplasts by electrophoresis on one- and two-dimensional polyacrylamide gels has revealed two major products and about 90 minor products¹⁰. One major product is tightly bound to the chloroplast lamellae, and is associated with the ATP-synthase complex¹⁰. The other major product is soluble, and has been identified as the large subunit of ribulose biphosphate carboxylase/oxygenase¹¹, the key enzyme in photosynthesis and photorespiration. This carboxylase (RBPCase) comprises up to 50% of the total soluble protein in leaves, and thus may be the most abundant protein in nature¹². The unusual abundance of this protein could account for the high proportion of ribosomes found inside chloroplasts. The RBPCase molecule is an oligomer of 16 subunits; 8 are termed large (molecular weight (MW) ~55,000) and carry the catalytic sites, while the other 8 are termed small subunits (MW ~14,000). The large subunit is encoded in chloroplast DNA¹³, and is synthesised from a messenger RNA lacking poly A (ref. 14). By contrast, the small subunit is encoded in nuclear DNA¹³; this subunit is not labelled when isolated chloroplasts incorporate labelled amino acids into protein but it has been identified as an *in vitro* translation product of cytoplasmic ribosomes¹⁵. We report here that the small subunit is synthesised as a precursor of higher molecular weight (20,000) when poly A-RNA from pea cytoplasmic ribosomes is translated by a heterologous protein-synthesising system. This precursor enters intact isolated chloroplasts with cleavage to the final size. In direct contrast to other systems where proteins cross membranes^{16,17}, this uptake and cleavage does not require concomitant protein synthesis. We propose that polypeptides enter the chloroplast after synthesis by a mechanism involving combination with specific sites in the chloroplast envelope.

Synthesis of precursor to the small subunit

When seeds of the pea plant (*Pisum sativum*) are germinated in darkness, the etiolated seedlings that result contain small amounts of RBPCase. If such seedlings are exposed to light, this enzyme accumulates rapidly as part of the development of chloroplasts that ensues¹⁸. Polysomes were prepared from etiolated pea apices after exposure to light for various periods by a method which minimises degradation by nucleases¹⁹. Total RNA was extracted from these polysomes and fractionated on a column of oligo dT-cellulose²⁰. The bound fraction containing poly A-RNA was then translated in the presence of ³⁵S-methionine by a protein-synthesising system prepared from wheat-germ²¹. Analysis of the products by one-dimensional electrophoresis on polyacrylamide gels containing sodium dodecyl sulphate (SDS) revealed many labelled bands. One band shows a marked and continuing rise in amount relative to the other bands when the poly A-RNA is isolated from apices exposed to light for progressively longer periods (Fig. 1). This band is specifically precipitated by rabbit antiserum prepared against purified pea RBPCase, but not by preimmune serum (Fig. 2). This immunoprecipitation is competed out by added RBPCase. Since the messenger RNA for the large subunit of RBPCase does not bind to oligo dT-cellulose in the conditions used¹⁴, we conclude that this band contains the small subunit polypeptide. This band has an apparent molecular weight of 20,000—about 6,000 greater than that of the small subunit prepared from purified pea RBPCase. These observations suggest that the small subunit is translated as a higher molecular weight

precursor from a messenger RNA containing poly A; we term this precursor P20. A similar precursor has been reported for the small subunit of RBPCase from *Chlamydomonas*²².

Fig. 1 Products of translation of pea leaf poly A-mRNA. Pea seedlings were grown in the dark for 9 d and then exposed to continuous white light (10,000 lx) for various periods of time. At intervals leaves were frozen in liquid nitrogen and ground to a fine powder. The powder was homogenised in 200 mM sucrose, 200 mM Tris-HCl, 60 mM KCl, 30 mM MgCl₂, pH 8.5 containing 1% (v/v) Nonidet P40 and 0.5% sodium deoxycholate (5 ml for every gram of frozen weight of powder). A polysome pellet was prepared from the homogenate as described previously¹⁹. RNA was extracted from the pellet as described by Brawerman²⁰. Oligo dT-cellulose chromatography was used to obtain poly A-RNA²⁰; LiCl rather than KCl was used because potassium dodecylsulphate comes out of solution readily. The poly A-RNA was used to programme a wheat-germ protein-synthesising system²¹. Each incubation contained in a final volume of 20 µl; 1 mM Tris-ATP, 0.1 mM GTP, 10 mM creatine phosphate, 0.05 mM of each amino acid except methionine, 10 mM dithiothreitol, 110 mM KCl, 2.5 mM Mg acetate, 250 µM spermidine, 50 µM spermine, 8.8 µCi ³⁵S-methionine (800 Ci mmol⁻¹) and 4 µg RNA. The mixture was incubated for 1 h at 27 °C and the trichloroacetic acid (TCA)-insoluble radioactivity determined as follows: aliquots were transferred to strips of Whatman No. 1 paper, heated to 90 °C in 10% TCA containing 0.1% (w/v) unlabelled methionine (10 ml per strip) for 20 min, washed with cold 10% TCA (20 ml per strip), followed by ethanol and ether. The dry strips were counted in 4 ml scintillant (0.5% PPO, 0.03% POPOP in toluene). The remaining assay incubations were prepared for gel electrophoresis by addition of sodium dodecyl sulphate (SDS) and 2-mercaptoethanol to final concentrations of 1% (w/v) and 2% (v/v), respectively, and 1/20 volume of 20×NURB (Neville upper reservoir buffer²⁷). The samples were heated to 95 °C for 2 min and then analysed on slab polyacrylamide gels as described by Laemmli²⁸, using a resolving gel which contained a linear gradient of 7.5–25% (w/v) acrylamide. Electrophoresis was for 16 h at 14 mA at room temperature; the gels were stained in 0.1% (w/v) Coomassie brilliant blue R in 45% methanol, 10% acetic acid and destained in successive changes of 45% methanol, 10% acetic acid. The gels were impregnated with PPO as described²⁹, and the sensitivity of the film increased by pre-flashing³⁰. The film was scanned by a Joyce-Loebl densitometer. The traces are of the products of poly A-RNA isolated from pea leaves greened for a, 24 h; b, 12 h. The arrow marks the band which increases relative to the other bands. Each gel track contains the same amount of TCA-insoluble radioactivity (150,000 c.p.m.); this amount of radioactivity was directed by 0.5 µg added RNA. Controls containing no added RNA incorporated 2,500 c.p.m. The following molecular weight markers were used: RBPCase large subunit (55,000); soybean trypsin inhibitor (25,000); myoglobin (18,000); cytochrome c (12,000).

Fig. 2 Identification of small subunit precursor by immunoprecipitation. The ^{35}S -labelled products of translation of poly A-RNA in the wheat-germ system were prepared as described in Fig. 1. After 60 min at 27 °C, the incubations were made up to 100 μl by addition of phosphate-buffered saline (PBS) containing bovine serum albumin (BSA) and Nonidet P40 to final concentrations of 100 $\mu\text{g ml}^{-1}$ and 1% (v/v) respectively. To each incubation 100 μg of rabbit immunoglobulin G (IgG) was added, and the mixture held at 37 °C for 60 min. The specific anti-RBPCase IgG was prepared as described by Shapiro *et al.*³¹, using antigen affinity columns and DEAE/CM-cellulose chromatography; the IgG from pre-immune serum was isolated by ammonium sulphate precipitation followed by the ion-exchange chromatography step. Antigen-antibody complexes were precipitated by addition of excess (10 mg) of heat-inactivated mixture were taken and kept on ice whilst chloroplasts were isolated as described previously¹¹. Chloroplasts from 15 g of 11-d-old pea leaves were washed once in isolation medium and resuspended in 6 ml of 25 mM HEPES-KOH, 110 mM KCl, 3 mM MgCl_2 , 10 mM dithiothreitol, pH 7.6. Aliquots (20 μl) of this suspension were added to the labelled products and incubated at 27 °C for the times stated; controls contained 20 μl resuspension buffer. Chlorophyll was measured by the procedure of Arnon³². *Staphylococcus aureus* (NCTC 8530)³². The *S. aureus* precipitates were washed twice with 250 μl of PBS containing BSA and Nonidet P40. The bound material was released by incubating the *S. aureus* at 50 °C in 200 μl of 10 mM Tris-HCl pH 7.4, 100 mM NaCl, 1 mM EDTA, 1% SDS, 1% 2-mercaptoethanol. The bacteria were removed by centrifugation and the supernatants prepared for polyacrylamide gel electrophoresis and analysed as described in Fig. 1. The tracks are as follows: a, total poly A-RNA-directed products, untreated; b, total poly A-RNA-directed products precipitated by anti-RBPCase IgG and *S. aureus*; c, as (b) but with preimmune serum instead of anti-RBPCase. The arrow indicates the small subunit precursor of apparent MW 20,000.

Processing of P20 to small subunit by intact isolated chloroplasts

Incorporation of ^{35}S -methionine into P20 by wheat-germ ribosomes programmed with pea poly A-RNA ceases after 60 min of incubation at 27 °C. When wheat-germ extract containing labelled P20 is subsequently incubated with preparations containing intact pea chloroplasts, there is a reduction in the amount of labelled P20 and an appearance of label in the small subunit region of the polyacrylamide gel (Fig. 3). The identity of the small subunit labelled by this procedure was confirmed by immunoprecipitation with antiserum to RBPCase (Fig. 4). When analysed by the two-dimensional method of O'Farrell²³, this processing is seen to introduce label into both the electrofocusing variants of the small subunit polypeptide that are found

in *Pisum sativum*. Two observations suggest that this processing step does not require concomitant protein synthesis by either cytoplasmic or chloroplast ribosomes. First, processing occurs after protein synthesis by the wheat-germ extract has ceased, as judged by amino acid incorporation measurements. And second, processing still occurs in the presence of either chloramphenicol (100 $\mu\text{g ml}^{-1}$) or cycloheximide (100 $\mu\text{g ml}^{-1}$). Chloramphenicol is a specific inhibitor of protein synthesis by chloroplast ribosomes, while cycloheximide is a specific inhibitor of protein synthesis by cytoplasmic ribosomes¹. While it is clear that processing does not require concomitant protein synthesis, it is still possible that it requires the presence of ribosomes. This possibility has been ruled out by our finding that processing still occurs even if ribosomes have been removed from the wheat-germ extract by centrifugation (data not shown).

Processing of P20 to small subunit occurs maximally in the presence of chloroplasts which retain their outer envelope (Table 1). Lysed chloroplasts and stromal preparations show some activity (40% and 25%, respectively, of the activity of an equivalent amount of intact chloroplasts). The preparation of lysed chloroplasts is unfractionated and thus still contains fragments of envelopes. The slight processing activity of the stromal fraction can be removed by centrifugation at 30,000 g_{av} (average) for 40 min. Preparations of chloroplast lamellae and heated chloroplasts (2 min at 90 °C) have no processing activity.

Fig. 3 Processing of P20 to small subunit by intact chloroplasts. Poly A-RNA was translated in the wheat-germ system as described in Fig. 1. After 60 min 10 μl aliquots of the incubation mixture were taken and kept on ice whilst chloroplasts were isolated as described previously¹¹. Chloroplasts from 15 g of 11-d-old pea leaves were washed once in isolation medium and resuspended in 6 ml of 25 mM HEPES-KOH, 110 mM KCl, 3 mM MgCl_2 , 10 mM dithiothreitol, pH 7.6. Aliquots (20 μl) of this suspension were added to the labelled products and incubated at 27 °C for the times stated; controls contained 20 μl resuspension buffer. Chlorophyll was measured by the procedure of Arnon³². Samples were prepared for polyacrylamide gel electrophoresis and analysed as described in Fig. 1. The traces are densitometer scans. Trace a, *in vitro* product incubated with buffer for 60 min; b, *in vitro* product incubated with chloroplasts (5 μg chlorophyll) for 0 min; c, *in vitro* product incubated with chloroplasts for 60 min. The arrow indicates the position of the small subunit.

These observations suggest that the processing enzyme is located in the chloroplast envelope.

The small subunit precursor reported from *Chlamydomonas*²² was also found to be processed to the small subunit, but in this case the processing activity was soluble. It is not possible to isolate intact chloroplasts from this alga; instead, extracts are prepared by the relatively violent method of passage through a French pressure cell. We therefore suggest that the soluble nature of the processing activity in this case may be a result of the procedures used, and not reflect its true location in the chloroplast envelope.

Transport of P20 into isolated chloroplasts

Our conclusion that the processing of P20 to small subunit requires the presence of chloroplast envelopes led us to see whether the small subunit would enter into the intact chloroplast. The commonly accepted criterion for the passage of a polypeptide across a membrane is the appearance of resistance to digestion by an added protease; this resistance should be abolished by the addition of detergents which disrupt membrane structure²⁴. Figure 5 shows the results of experiments designed to apply this criterion to the processing of P20 by intact chloroplasts. The results clearly show that the small subunit produced when labelled P20 is incubated with intact chloroplasts is resistant to hydrolysis by trypsin (track c), unless detergent is added at the same time (track d). Other low molecular weight polypeptides synthesised from poly A-RNA by the wheat-germ extract are all digested by trypsin, even in the absence of detergent. The product with the mobility of small subunit seen in track a was shown not to be authentic small subunit by tryptic peptide analysis (data not shown).

Mechanism for polypeptide transport into chloroplasts

The signal hypothesis provides an attractive mechanism for explaining how polypeptides which are secreted by cells are

Fig. 4 Identification of product of *in vitro* processing of P20. Poly A-RNA was translated in the wheat-germ system and the labelled polypeptides obtained incubated with intact chloroplasts as described in Fig. 3 except that 10 μ l of wheat-germ incubation mixture was incubated in a final volume of 60 μ l with chloroplasts containing 6.8 μ g chlorophyll. After 60 min at 27 °C the chloroplasts were lysed by addition of Nonidet P40 to 1% (w/v) and the volume made up to 200 μ l with PBS. Aliquots (100 μ l) were analysed by immune precipitation and gel electrophoresis as described in Fig. 2. Electrophoresis was from left to right and autoradiography was for 7 d at -70 °C. The lines are densitometer scans. a, Total poly A-RNA-directed products incubated with intact chloroplasts; b, the polypeptides from a, which bind to anti-RBPCase IgG; c, as (b) but using pre-immune IgG. The arrow marks the position of RBPCase small subunit.

Table 1 Processing of P20 by chloroplast fractions

Incubation for 60 min in the presence of:—	Processing activity
Buffer	0
Intact chloroplasts	100
Lysed chloroplasts	40
Low speed stroma	25
High speed stroma	< 5
Thylakoids	0
Boiled chloroplasts	0

Poly A-RNA was translated in the wheat-germ system as described in Fig. 1. After 60 min, 10 μ l aliquots of the incubations were taken and kept on ice whilst chloroplasts were isolated as described in Fig. 3. Two pellets of chloroplasts were obtained. One was resuspended in 6 ml of 25 mM HEPES-KOH, 110 mM KCl, 3 mM MgCl₂, 10 mM dithiothreitol, pH 7.6 (intact plastid buffer); this preparation is referred to as intact chloroplasts. The other pellet was resuspended in 3 ml of 10 mM HEPES-KOH, 10 mM dithiothreitol, pH 7.6 followed by 3 ml of 2 \times intact plastid buffer; in this preparation all the chloroplasts are lysed. An aliquot (1 ml) of the intact chloroplast suspension was placed, for 5 min, in a boiling waterbath; this gave a boiled chloroplast preparation. An aliquot (4 ml) of the lysed chloroplast preparation was centrifuged at 4,000 g for 5 min, the supernatant was removed and the pellet resuspended in 4 ml of intact plastid buffer. The two fractions are referred to as low speed stroma and thylakoid preparations respectively. Half of the low speed stroma was centrifuged for 40 min at 30,000g_{av}; this gave high speed stromal preparation. Equal volumes of each preparation were added to the labelled products and incubated, in a final volume of 50 μ l, at 27 °C for the times stated. Chlorophyll was measured by the procedure of Arnon²⁵; each incubation contained the equivalent of 4.7 μ g of chlorophyll. Samples were prepared for polyacrylamide gel electrophoresis and analysed as described in Fig. 1. The autoradiographs were scanned on a Joyce-Loebl microdensitometer. The processing activity was determined by comparing the absorbance of the P20 band at 0 and 60 min. Incubation with intact chloroplasts caused a 60% reduction in this absorbance; this decrease was arbitrarily defined as 100 units of activity.

synthesised by membrane-bound ribosomes and transported into the lumen of the endoplasmic reticulum^{16,17}. According to this hypothesis, secreted polypeptides are encoded by messengers which specify an N-terminal sequence of amino acids, whose appearance on the polysome causes the latter to bind to the membrane of the endoplasmic reticulum. The growing polypeptide chain is then inserted through a tunnel in the membrane formed by the association of the signal sequence with membrane proteins; protease activity in the membrane rapidly removes the signal sequence. A key feature of this mechanism is that the transport through the membrane depends upon concomitant protein synthesis by membrane-bound ribosomes, since the polypeptide chain moves through the tunnel in an extended form as it is being lengthened.

Application of this hypothesis to the transport of polypeptides into chloroplasts predicts that the outer chloroplast envelope should be studded with bound ribosomes during the development of the organelle. However, it is apparent from many electron microscopic studies that the chloroplast envelope never presents a similar appearance to rough endoplasmic reticulum. To overcome this objection, a modified signal hypothesis may be considered, in which the chloroplast polypeptides are first inserted into vesicles of endoplasmic reticulum which subsequently fuse with the chloroplasts.

It is clear from the evidence we have presented that the transport of the small subunit of RBPCase into the chloroplast proceeds by a mechanism different from that envisaged by the signal hypothesis. This transport proceeds after synthesis of the precursor has ceased, and in the absence of cytoplasmic ribosomes. Additional evidence consistent with this conclusion is the observation that the small subunit of *Chlamydomonas* is synthesised by free cytoplasmic ribosomes in the absence of membranes²². All these observations are consistent with the

Fig. 5 Transport and processing of P20 by intact chloroplasts. Poly A-RNA was translated in the wheat-germ system and the labelled polypeptides obtained were incubated with intact chloroplasts as described in Fig. 4. At the end of the incubation, TPOCK-treated trypsin was added to a final concentration of $100 \mu\text{g ml}^{-1}$ and the mixture incubated at 30°C for 30 min. To some samples Nonidet P40 (final concentration 1% (v/v) was added at the same time as the trypsin. Samples were analysed as in Fig. 2. Track *a*, polyA-RNA-directed products incubated in buffer without chloroplasts for 60 min followed by a further 15 min in the absence of trypsin; *b*, poly A-RNA-directed products incubated with chloroplasts for 60 min followed by 15 min in the absence of trypsin; *c*, as (*b*), but the final incubation was with trypsin; *d*, as (*c*), but the final incubation was with Nonidet P40 as well as trypsin. P20, small subunit precursor; SSU, small subunit of RBPCase.

envelope carrier hypothesis which was first suggested to account for the transport of polypeptides into chloroplasts when it was demonstrated that isolated chloroplasts synthesise the large but not the small subunit of the RBPCase¹¹. This hypothesis states that a class of proteins exists in the chloroplast envelope which recognises sites common to all those proteins which are made on cytoplasmic ribosomes, but which are destined to function in the chloroplast. In this hypothesis the recognition site on the entering polypeptide need not be at the N-terminus.

The weakness of the envelope carrier hypothesis is that while it accounts for the specificity of transport, it does not propose a mechanism for the actual movement of the polypeptide through the envelope. However, analysis of the processing of P20 on electrofocusing gels shows that P20 has a much lower isoelectric point (by 1.0–1.5 pH units) than either of the two electrofocusing variants of the mature small subunit. This observation suggests that the extra sequence(s) in P20 contain acidic amino acids; known signal sequences, by contrast, are rich in hydrophobic amino acids and contain few, if any, acidic amino acids³⁴.

Fig. 6 Postulated model for RBPCase synthesis in higher plants. nDNA and cDNA stand for nuclear and chloroplast DNA respectively. The dashed line indicates possible control sites at which small subunit affects synthesis of large subunit (modified from ref. 5).

Removal from P20 of such a large number of amino acids (around 50), many of which are charged, is likely to cause a conformational change in the polypeptide. We therefore propose that the transport of P20 into chloroplasts involves combination with a specific carrier in the chloroplast envelope. Protease activity in the envelope then removes part of the polypeptide, which triggers a conformational change leading to the transport of the small subunit across the envelope and release into the stroma.

Aspects of the envelope carrier hypothesis are testable by established techniques. Purified preparations of pea chloroplast envelope can be made²⁵, and will be tested for combination with and processing of P20. The physical state of the small subunit inserted into both intact chloroplasts and purified envelopes will be determined to see whether combination with the large subunit is necessary for the release of the small subunit into the stroma. It is possible that part of the sequence difference between P20 and the small subunit is necessary for the assembly of the RBPCase molecule: this would account for the difficulty in reconstituting active RBPCase molecules from isolated subunits. The suggestion that the small subunit is required for the continuing translation of the messenger for the large subunit⁵ can also now be tested.

Figure 6 summarises our current model for the synthesis of RBPCase in eukaryotic plant cells. The principles exemplified by this model may be of general application to the synthesis of the many proteins found in both chloroplasts and mitochondria. It has been established for each of at least three mitochondrial proteins that their subunits are made in different cellular compartments, for example, three of the seven subunits of cytochrome *c* oxidase are synthesised by mitochondrial ribosomes while the other four are made in the cytoplasm³⁵. The cytoplasmic subunits have been reported to exert a specific and positive effect on the synthesis of the other three subunits by isolated mitochondria in the absence of cytoplasmic protein synthesis³⁶. This finding suggests that in the case of mitochondria as well as chloroplasts, cytoplasmically synthesised polypeptides enter the organelle by an envelope carrier type of mechanism, and control the synthesis of the polypeptides with which they ultimately associate.

letters to nature

Cosmic ray source abundance of calcium

MEASUREMENTS of the charge composition of cosmic ray nuclei have led to the belief that cosmic ray calcium nuclei originate in about equal proportions from the sources and from spallation in the interstellar medium¹. The primary calcium is thought to be essentially ⁴⁰Ca, as in the Solar System, while from nuclear reaction systematics the spallative calcium should be mainly ⁴²Ca, ⁴³Ca and ⁴⁴Ca. Simpson *et al.*², however, have presented some surprising results of a measurement of the isotopic composition of calcium in cosmic rays. They found that calcium is largely ⁴²Ca, and they did not see any ⁴⁰Ca. They concluded that calcium is absent at the source, and to account by spallation only for the measured abundances they assumed that the cross-sections for production of Ca by spallation of Fe are much larger than those calculated by Silberberg and Tsao's formula³. A very low calcium abundance in the source would be a major difference with the Solar System, and an experimental determination of the calcium production cross-sections is essential to settle this point. In a report on results of measurements of cross-sections for production of stable nuclides by spallation of Fe (ref. 4) we emphasised the element group Sc-Mn, but some results have also been obtained for Ca, as a byproduct⁵. We considered these as preliminary, and no cross-section value was given for this element. The measurement of Simpson *et al.*² has motivated us to re-examine our calcium data. The cross-sections we

Although the experiment was not specially designed for calcium, this problem was not so crucial here, because of the large difference in isotopic composition between the spallative calcium and the natural one. Contamination is dominant only for ⁴⁰Ca, which represents 97% of natural calcium, but this is not important because the cross-section of ⁴⁰Ca is very small³. On the other hand, isotopes with larger cross-sections have very low natural abundances, so that the contamination, as deduced from the mass-40 peak, is only a few per cent for ⁴²Ca and ⁴³Ca, and at most ~20% for ⁴⁴Ca.

In Table 1, we give the measured isotopic ratios, corrected for contamination, and isotopic discrimination of the mass-spectrometer. Two determinations have been performed at 600 MeV, and one at 21 GeV. The first three ratios give the relative composition of the four isotopes with the largest cross-sections. These are the most precisely measured. As we need the radioactive isotope ⁴⁵Ca (*t*_{1/2} = 165 d) for deriving absolute cross-sections, we also give two ratios relative to this radioisotope. The larger uncertainties in this case are due to both the smaller cross-sections of ⁴³Ca and also to the scandium contribution to the mass-45 peak.

Because ⁴³Ca is pure β⁻-emitter, measurements of the cross-sections are difficult and few have been reported; 1.20 ± 0.13 mb is given at 660 MeV, 1.4 ± 0.2 mb at 730 MeV, and 0.69 ± 0.14 mb at 24 GeV (refs 6, 7, 8 respectively). We do not know of a more recent determination. The good agreement between the values at 660 and 730 MeV gives

Table 1 Ratios of cross-sections for calcium production by spallation of iron, measured by mass-spectrometry

	⁴¹ Ca/ ⁴² Ca	⁴³ Ca/ ⁴² Ca	⁴⁴ Ca/ ⁴² Ca	⁴² Ca/ ⁴⁵ Ca	⁴⁶ Ca/ ⁴⁵ Ca
600 MeV	0.36 ± 0.05	1.18 ± 0.11	1.24 ± 0.14	9.1 ± 2.0	0.27 ± 0.07
21 GeV	0.42 ± 0.06	1.08 ± 0.10	1.10 ± 0.15	9.5 ± 2.8	0.23 ± 0.07

have derived and reported here, although not of the precision we would like, allow a safe enough conclusion on the Ca source abundance.

The experimental procedure has been described elsewhere^{4,5}. We recall that ultra-high purity iron targets were irradiated by protons from the two CERN accelerators (600 MeV and 21 GeV); the spallation products were then chemically separated, and their isotopic composition determined by mass spectrometry. The cross-sections of stable isotopes were obtained with respect to those of radioactive isotopes, measured by classical nuclear physics techniques.

One of the major problems in measuring small quantities of stable isotopes is the contamination by natural impurities.

us some confidence but a new measurement, at least at high energy, would be desirable. Combining these values with our measured isotopic ratios, we derive the absolute cross-sections given in Table 2. These are cumulative cross-sections—including the contributions from short-lived isobars.

The data of Simpson *et al.*² were obtained at ~ 500 MeV m⁻¹. Taking into account solar modulation and interstellar energy loss, the relevant cross-sections should be taken, typically, around 1 GeV. On the basis of known excitation functions, cross-sections at this latter energy are expected to be of the same order as, or slightly larger than those at 600 MeV. Our values are considerably smaller than those adopted by Simpson *et al.*² (70 mb for total Ca,

Table 2 Experimental cross-sections (mb) for calcium production by spallation of iron, compared with Silberberg and Tsao's calculations

	⁴¹ Ca	⁴² Ca	⁴³ Ca	⁴⁴ Ca	⁴⁵ Ca	⁴⁶ Ca
600 MeV	3.9 ± 1.2	10.9 ± 2.7	12.9 ± 3.1	13.5 ± 3.0	1.20 ± 0.13*	0.32 ± 0.09

*Normalisation, ref. 6 (660 MeV), ref. 7 (24 GeV).

†Ref. 3.

27 mb for ^{42}Ca). At 600 MeV, they agree quite well with those calculated by Silberberg and Tsao's formula³, also given in Table 2. The large discrepancy at high energy is essentially due to our normalising to the ^{42}Ca cross-section measured by Estrup⁸, which is almost a factor of 2 smaller than the calculated one; the disagreement on isotopic ratios is much smaller.

An independent upper limit of the ^{42}Ca cross-sections can be deduced from our scandium measurements⁴. At 600 MeV we made six determinations of the spallation isotopic ratio $^{45}\text{Sc}/^{46}\text{Sc}$, and four at 21 GeV, at times after irradiation varying from 1 d to 280 d (when about 70% of ^{42}Ca had decayed to ^{45}Sc). We observed no systematic increase of this ratio with time, and all values agreed within 2% at 600 MeV, and 5% at 21 GeV, well within experimental uncertainty. This yields conservative upper limits of the ^{42}Ca cross-sections of ~ 1.7 mb at 600 MeV, consistent with the measured value⁸, and ~ 1.8 mb at 21 GeV. The derived upper limits at high energy for ^{42}Ca and total Ca are thus still lower than Simpson *et al.*'s assumption².

We conclude, therefore, that in spite of the rather large uncertainties of our results, it is very unlikely that the observed cosmic ray calcium abundance can be entirely due to interstellar spallation. Moreover, in secondary calcium, ^{42}Ca , ^{43}Ca and ^{44}Ca should have about the same abundance. Thus, the previous assumption that calcium is present in the source with an abundance ~ 10 –15% that of iron is probably correct, but if one accepts the data of Simpson *et al.*² the source calcium must be mainly ^{42}Ca . This would be an enormous difference with Solar System abundances. In addition, measurement of the isotopic composition of other primary cosmic ray species^{9,11} show that they are all consistent with Solar System composition, although there are claims for some enhancement of neutron-rich isotopes of Ne (ref. 9) and Fe (ref. 2). Thus, one would have to find a process of nucleosynthesis which would not only make more ^{42}Ca than ^{40}Ca but at the same time leave all other elements with 'normal' composition. This seems to be quite difficult and considering the low statistics of the calcium measurement of Simpson *et al.*², it seems reasonable to wait for further confirmation of the strange isotopic composition of cosmic ray calcium.

The experimental work was carried out while I was with Laboratoire René Bernas, Orsay, France.

Interpretation of observed cosmic microwave background radiation

ALFVEN and Mendis¹ concluded recently that dust grains in galaxies rendered the Universe opaque to the cosmic microwave background at a red shift of $z = 40$, instead of the generally accepted value of $z = 1,500$. This is highly significant because the microwave background is usually believed to be evidence for a

very hot, dense phase of the Universe². If we can see no further back than $z = 40$, then one objection to nonstandard³ (no big bang) cosmological models is removed. I present here some arguments to show that their assumptions are unreasonable and that a proper calculation in the standard big bang model shows that dust grains are transparent to the microwave background.

Alfven and Mendis¹ calculated the opacity of galactic dust grains by integrating over the metagalaxy at one epoch. A proper treatment would integrate back in time from the present epoch. This alone reduces their estimate of the opacity by a factor of ~ 5 . They also assumed no evolutionary effects in their calculations. But the dust grains are thought⁴ to consist of CH_4 , NH_3 and H_2O with silicate or graphite cores. The mantles sublime⁴ at 100 K, which was the temperature at epoch $z = 36$. The remaining cores have an absorption cross-section roughly 10 times lower⁵ than the ice-coated grains. Another important evolutionary effect concerns the nucleosynthesis of the elements that make up the grains. In the standard big bang model, elements as heavy as oxygen and silicon could not be synthesised in the big bang itself⁶. They must have been synthesised in stars, most likely at an epoch no earlier than $z = 65$. Thus dust grains could not have existed in significant amounts before this era. This will be discussed in more detail later.

Alfven and Mendis¹ calculated the opacity for 1.8 mm microwaves, which they used as the representative wavelength of the cosmic black body radiation. Galactic dust grains, however, are more transparent to longer wavelengths. Observations of the radiation have been made at varying wavelengths⁷ up to 73.5 cm, for which the expected opacity of the grains is less by a factor of 400.

The value of the deceleration parameter q_0 is not well known. Alfven and Mendis used $q_0 = 0.03$. If $q_0 = 0.5$ (flat space), then the opacity of dust grains is reduced by a factor of 4 for a given epoch z . This is because a large deceleration means that the cosmic expansion was faster in the past, so that a ray of light spent less time in any given epoch. A value of 0.5 for q_0 does not contradict any data.

The optical depth τ , for a given wavelength λ_0 along a path from the present era to a past epoch of red shift z_0 , is given by

$$\tau(\lambda_0) = \int_0^{z_0} n(z)\sigma(\lambda)dl \quad (1)$$

where σ is the scattering or absorption cross-section per grain, and n is the number density of the grains. The number of dust grains in a comoving volume remains constant, except for evolutionary changes. As the volume increases as $(z+1)^{-3}$, the number density increases as

$$n(z) = (z+1)^3 f(z) n(0) \quad (2)$$

where $f(z)$ contains all evolutionary effects such as the nucleosynthesis of elements that make up the grains, and is normalised to $f(0) = 1$.

In a matter-dominated Friedmann universe (standard big bang model), a straightforward but messy calculation shows that we can express dl as

$$dl = -cdt = (c/H_0)(z+1)^{-2}(1+2q_0z)^{-1/2} dz \quad (3)$$

Starting with a measurement of $\sigma(\lambda)$ at $\lambda = 0.55 \mu\text{m}$, Alfven and Mendis¹ assumed that $\sigma(\lambda) \propto 1/\lambda$ and extrapolated $\sigma(\lambda)$ to $\lambda_0 = 1.8 \text{ mm}$. Detailed models of the grains⁵ support this functional dependence in a rough way. The evaporation of the grain mantles, however, requires that the opacity drops sharply when the temperature rises above 100 K. This occurred for all epochs

before $z = 36$. As $\lambda \propto R \propto (z+1)^{-1}$ where R is the cosmic scale factor, we can write

$$\sigma(\lambda) = (z+1)g(z)\sigma(\lambda_0) \quad (4)$$

where

$$g(z) = \begin{cases} 1.0 & z < 36 \\ 0.1 & z > 36 \end{cases} \quad (5)$$

Combining equations (1), (2), (3) and (4) we obtain

$$\tau(\lambda_0) = (c/H_0)n(0)\sigma(\lambda_0) \int_0^{z_c} (z+1)^2 f(z) g(z) (1+2q_0 z)^{-1/2} dz \quad (6)$$

At optical wavelengths, the optical depth of our Galaxy parallel to its polar axis is roughly⁸ 0.5. Let D , S_g and n_g be the thickness, area and dust density of the dusty region of our Galaxy. Then

$$Dn_g\sigma(0.55 \mu\text{m}) = 0.5 \quad (7)$$

and

$$n(0) = DN_{og}S_g n_g \quad (8)$$

where N_{og} is the number density of galaxies. Alfven and Mendis used values of $S_g = 5 \times 10^{45} \text{ cm}^2$ and $N_{og} = 1.2 \times 10^{-75} \text{ cm}^{-3}$, both of which are reasonable estimates. Combining these values with equations (7), (8) and $\sigma(\lambda) \propto 1/\lambda$ gives

$$n(0)\sigma(\lambda_0) = 1.65 \times 10^{-33}/\lambda_0(\text{mm}) \text{ (in cm}^{-1}\text{)}. \quad (9)$$

For⁹ $H_0 = 55 \text{ km (s-Mpc)}^{-1}$,

$$c/H_0 = 1.6 \times 10^{28} \text{ cm}, \quad (10)$$

which is the same value Alfven and Mendis used for R_0 .

The only thing needed to finish the calculation of the opacity of the galactic dust grains is the evolution of dust grain density, represented by the function $f(z)$. As dust grains are composed mostly of heavy elements, restrictions on the heavy element abundances will restrict grain densities. Observations of external galaxies by Strom *et al.*¹⁰ show gradients of metal abundances, with the outer regions containing fewer heavy elements than the nuclei. This can be explained¹¹ only by assuming that stellar formation took place during galaxy formation, not before. As stars formed in a predominantly gaseous infall, their nucleosynthesis and subsequent deaths as supernovae (or their stellar winds) enriched the galactic cores more so than the outer regions. I assume that before the Galaxy formed, there was some initial abundance of heavy elements from pregalactic stars. To estimate this abundance, I use the observed heavy element abundance of the poorest metal containing globular clusters, since they are thought to be the oldest objects that can be seen¹². Their metal abundances are roughly 1/300 that of the Sun¹², so $f(z > z_g) = 0.003$, where z_g is the epoch of Galaxy formation. If we assume that our Galaxy started as a spherical cloud that collapsed to a disc, the observed mass and radius of the Galaxy gives a free fall time of roughly $(r^3/GM)^{1/2} \approx 100 \text{ Myr}$. As the epoch $z = 65$ occurred about 100 Myr after the big bang, the galaxies couldn't form earlier than the epoch $z = 65$. Thus an upper bound for $f(z)$ is

$$f(z) = \begin{cases} 1.0 & z < 65 \\ 0.003 & z > 65 \end{cases} \quad (11)$$

Combining equations (5), (6), (9), (10) and (11) enables us to do the integral and calculate $\tau(\lambda_0)$. Recent measurements¹³ of the black body anisotropy used a wavelength of $\lambda_0 = 9 \text{ mm}$. At

$z_c = 1,500$, the generally accepted value of decoupling, the optical depth due to absorption by galactic grains is $\tau(9 \text{ mm}) = 0.18$ for $q_0 = 0.03$ and $\tau(9 \text{ mm}) = 0.05$ for $q_0 = 0.5$. Thus most of the light emitted at the time of decoupling has reached us unscattered by intervening dust.

To conclude, I have calculated the opacity of galactic dust grains to the microwave background radiation from the time of decoupling at $z_c = 1,500$ to the present in the standard big bang model. I have estimated evolutionary effects on grain opacity and abundance, conservatively overestimating the expected grain density. At typical wavelengths used in studying the microwave background, I have shown that the optical depth of the grains is only 0.18 for $q_0 = 0.03$ and is 0.05 for $q_0 = 0.5$. Thus the microwave background can give us information on an early dense phase of the Universe.

I thank Drs C. McKee, A. Buffington, R. Muller and G. Smoot for reviewing this paper; Drs C. Orth and T. Tyson for helpful discussions, and Dr H. Alfven for a very stimulating discussion. This work was supported by NASA.

Plasma fluxes between ionosphere and protonosphere

PLASMA flux between ionosphere and protonosphere is important for our understanding of ionospheric-magnetospheric coupling. Attempts have been made to deduce the H^+ flux between ionosphere and protonosphere from incoherent scatter observations of O^+ densities and vertical velocities in the topside ionosphere^{1–4}, but theoretical studies⁵ have suggested that the O^+ flux is not necessarily related in a simple way to the H^+ flux and may even at times be in the opposite direction. More direct estimates of average daytime and night-time fluxes have been calculated from a limited data base of whistler observations of tube content⁶, while topside electron density profiles have also been used⁷.

The ATS-6 radio beacon experiment⁸ provides a method of estimating integrated net ionospheric-protonospheric fluxes on a continuous basis from the temporal changes in protonospheric content. The receiving station at Aberystwyth (52.42°N, 4.05°W) for transmissions from the ATS-6 satellite (geostationary above 35°E) allowed determination of both the plasmaspheric group delay and the ionospheric polarisation rotation. The former is related directly to the total electron content (N_T) along the slant path from satellite to receiver while the latter gives a measure of the Faraday electron content (N_F) along the ionospheric part of the path.

Model studies^{15–17} have shown that using an average longitudinal gyrofrequency for the path, evaluated at a fixed height in the range 350–420 km, in the conversion of polarisation rotation to Faraday content produces values which give a measure of the electron content up to an effectively constant altitude between 2,000 and 3,000 km. For geometry applicable to the present study the height sensitivity of the longitudinal

gyrofrequency is small, differing, over the height range 300 to 500 km, by less than $\pm 1.3\%$ from the chosen value for 420 km.

From the difference between N_T and N_F measurements made to a sufficient degree of accuracy, the electron content of the protonospheric part of the path (N_p) can be obtained. In practice, N_p is a measure of the content from $\sim 2,500$ km altitude to the plasmapause, estimated to an absolute accuracy within $\pm 15\%$, but with much better relative accuracy allowing small temporal changes to be studied. The protonospheric content expressed as a percentage of the total ranges in general from some 15–20% by day to 30–40% by night.

Temporal changes of protonospheric content are indicative of the filling and draining of this region where production and loss processes are unimportant so that the ionospheric–protonospheric flux can be obtained from the temporal gradient of the protonospheric content (dN_p/dt). It should be noted that the protonospheric content measured by the ATS-6 experiment refers to a slant path to the satellite which intersects a wide range of L -value flux tubes, as shown in Fig. 1 for Aberystwyth geometry up to $L = 4$. The protonospheric flux estimated from ATS-6 measurements is thus an integrated parameter over these tubes in contrast to the more direct measurements of flux, essentially along a particular field tube, given by the whistler and incoherent scatter techniques.

Monthly median diurnal values of N_p have been used to estimate the temporal rate of change of this parameter (dN_p/dt), calculated for each hour. To reduce the scatter in the data points, the N_p values were first filtered using a 3-h running mean before calculating the gradients. The diurnal variations of the fluxes for December 1975 and January 1976, representing northern hemisphere winter, and June and July 1976 corresponding to summer conditions are shown in Fig. 2. Positive values are indicative of an upwards flux filling the tubes with negative values corresponding to downwards depletion. The highly intermittent nature of the beacon transmissions, particularly while the satellite was eclipsing, have prevented reliable flux data being obtained for the equinoctial season.

To help explain some of the observed features of the diurnal variations of the integrated flux, the sunrise and sunset times, in both local (47°N , 22°E) and conjugate (35°S , 37°E) hemispheres at 350 km, at the ionospheric base of the $L = 2$ flux tube, which intersects the ATS-6 ray path at $\sim 5,000$ km altitude, are marked on Fig. 2.

In interpreting Fig. 2 it must be remembered that the satellite crosses many field lines at different heights, the ionospheric feet of which become sunlit at different times. Figure 1 indicates the range of latitudes of the ionospheric terminations of the field lines within the plasmasphere below $L = 4$, but taking account of the longitudinal range as well, the spread of sunrise and sunset times for the feet of the relevant field lines in both local and conjugate hemispheres can exceed ± 1 h about the times shown in Fig. 2. A second factor to consider is the time constant between an increase in ionospheric ionisation and the appearance of enhanced protonospheric plasma. A time constant ~ 1 h has been suggested for the diffusive barrier at the O^+/H^+ transition height⁹, while the travel time of ions

Fig. 1 Geomagnetic field line configuration for ATS-6 to Aberystwyth ray path.

Fig. 2 Diurnal variations of the integrated protonospheric flux (dN_p/dt) for Aberystwyth for *a*, December 1975, *b*, January, *c*, June and *d*, July 1976. The arrows mark the times of sunrise and sunset in both local and conjugate hemispheres at the terminations at ionospheric height (350 km) of the $L = 2$ field line which intersects the ray path at $\approx 5,000$ km altitude. \uparrow , local sunrise; \downarrow , local sunset; \uparrow , conjugate sunrise; \downarrow , conjugate sunset.

to the protonosphere even at thermal speed may considerably exceed 1 h depending on the field line path. Thus the overall time constant may be of the order of several hours.

Considering first the Northern Hemisphere summer curves represented by June and July in Fig. 2, it can be seen that upwards fluxes start some 2 h after local sunrise with maximum values some 2 h after conjugate sunrise. The subsequent decrease in the flux rate may indicate that the relatively short small volume tubes of low L -value (say $L \leq 2$) become well filled so that the upwards flux to them is decreased and the subsequent small increase in protonospheric content occurs on the large volume higher L -value flux tubes¹⁰. The rates of change do not differ significantly from zero in the middle of the summer day when the neutral wind is depressing the F-layer ionisation, but after conjugate sunset a large downwards flux quickly develops. It is interesting that this downwards flux maximises at about the time of the second daytime ionisation peak in the still sunlit local ionosphere. This suggests that the protonospheric depletion at this time is to the conjugate ionosphere and the shape of the flux variation, quickly maximising downwards with subsequent smaller magnitudes, seems to indicate that the short inner tubes are quickly drained. The northern hemisphere winter curves represented by December and January show an upwards flux following sunrise in the local hemisphere and a sunset associated depletion. It is also interesting that a short lived upwards flux can be found around conjugate sunrise for these months when the time separation between sunrise in the two hemispheres is a maximum. This net upwards flux is of short duration, however, and the enhanced losses and effective downward movement of the local ionosphere evidenced by the well-known pre-dawn electron density depletion more than compensate for conjugate induced enhancements. A net decrease in protonospheric content is thus found until after local sunrise.

The average integrated fluxes obtained in the present study show that to within the accuracy of the estimates the upwards flux by day in magnitude and duration is broadly compensated by the downwards flux at night. Park⁶ from whistler observations has estimated average flux magnitudes generally greater than the levels indicated by the present study, with the average daytime upwards flux exceeding the downwards night-time flux by a factor of 2. While the present results are based on monthly median protonospheric content data, the values in

Park's case study refer to a post-storm period during which the protonosphere is being replenished with daytime refilling exceeding night-time draining. Additionally, his observations are for tubes with $L > 4$ while the Aberystwyth ray path crosses tubes with $L \geq 1.7$ and it has been argued that the flux is enhanced for higher L -shells because of the relatively less dense plasma in these larger volume tubes¹⁰.

It can be concluded from this study that both local and conjugate ionospheres play important parts in the filling and depletion of the protonospheric flux tubes; a result supported by recent theoretical work¹¹. Thus in the interpretation of protonospheric content data corresponding to observations along the line of sight to a geostationary satellite, ionospheric-protonospheric interactions in both hemispheres must be considered. This conclusion enables us to account for the significant differences found between ATS-6 observations of protonospheric content made in Europe and USA. A set of protonospheric content data for July 1974 to May 1975 from ATS-6 observations made at Boulder, USA (40°N, 105°W) has been published¹². These monthly median values of N_p converted to local mean time show a daytime minimum in protonospheric content in winter and very low values in summer. By contrast, the Aberystwyth data (albeit for a later year but still near solar minimum) have a daytime maximum at all seasons with winter night-time magnitudes comparable to those at Boulder, but in summer the European content can be more than double that of the America station. A detailed examination¹³ shows that, in addition to the effects of observational sensitivities, these differences may be explained in terms of ionospheric-protonospheric interactions in both hemispheres, remembering that the nonalignment of the geographic and geomagnetic axes results in an ionosphere conjugate to Boulder which is sub-Antarctic in location (57°S, 105°W). The anomalous behaviour of the continuously sunlit Antarctic ionosphere in local summer (December-January) under the influence of the neutral wind is well documented¹⁴, and this factor, together with the long winter nights and the generally higher L -shells intersecting the Boulder ray path, may account for the differences between the European and American protonospheric contents.

We thank Professor Sir Granville Beynon, FRS for his interest in the planning of ATS-6 observations in UK. The cooperation of Dr E. N. Bramley and Mr L. J. Martin of Appleton Laboratory and Dr J. K. Hargreaves and Dr S. Ganguly of University of Lancaster in the ATS-6 project is gratefully acknowledged. Post-geomagnetic storm protonospheric replenishment

THE response of the ionosphere to geomagnetic storms is well documented¹⁻³, although the complex interaction of the various physical mechanisms is not yet fully explained. However, the response of the overlying protonosphere to geomagnetic activity, a topic important to the understanding of ionospheric-magnetospheric coupling has not been widely studied. A direct study of tube content recovery obtained from whistler observations during an 8-d period in June 1965 following a sudden commencement storm has been published by Park⁴, although theoretical work⁵ has given a value for the replenishment time constant which is larger than that observed. We report here the results of protonospheric content observations during a period where a major sudden commencement storm was followed by an exceptionally long period of quiet allowing complete dynamic saturation of the protonospheric flux tubes to be reached.

The ATS-6 radio beacon experiment⁶ carried out at Aberystwyth (52.42°N, 4.05°W), while the geostationary satellite was stationed at 35°E longitude, allowed estimates to be made of both the plasmapheric total electron content (N_T) and the ionospheric Faraday electron content (N_F) to sufficient accuracies that the protonospheric electron content along the slant path (N_p) could be obtained from the difference. We report here the results of protonospheric electron content measurements during the period 28 April to 21 May 1976. Hourly values of N_p available throughout the period are plotted in Fig. 1. Also shown for comparison, recurring for each day, is a plot of the diurnal variation of the averaged hourly N_p for May 1976. Values of the 3-h K_p index are presented above the corresponding N_p data. The period starts with 4 d in which the geomagnetic activity reaches $K_p=4_+$ late on 29 April and N_p shows a fluctuating pattern, particularly on 30 April and 1 May when the diurnal variation is almost masked by apparently random variations. A major storm with sudden commencement at 1828 UT on 2 May and K_p reaching 8_+ is preceded by a sharp increase in N_p around midday to be followed by a depletion with N_p reaching very low values on the morning of 3 May and even lower magnitudes around midnight of that day. In fact this value $1.3 \times 10^{16} \text{ m}^{-2}$ was the lowest N_p value found at Aberystwyth during the 9-month observing period. Three days follow with substantial breaks in the N_p data due to non-continuity of the satellite transmissions, but the values plotted show the trend of a replenishing protonospheric content which is continued until about 16 May during a time of quiet geomagnetic activity. Superposed on this trend is a regular diurnal variation with increasing amplitude as the quiet period continues. From 16 to 19 May the geomagnetic activity is very low and N_p is consistently above average with a continuing clear large diurnal variation. It therefore seems that the depleted protonosphere of 3 May requires some 14 d of quiet conditions with steady diurnal partial filling and draining to reach a quasi-equilibrium situation about 16 May. Thus from 16 to 18 May the protonospheric content for ATS-6 to Aberystwyth geometry presents its saturated dynamic equilibrium pattern for quiet geomagnetic activity with values maximising around $7 \times 10^{16} \text{ m}^{-2}$ during daytime filling and depleting to about $4 \times 10^{16} \text{ m}^{-2}$ at night. The maximum and minimum values of N_p for each day both increase steadily from the storm depletion with the daytime filling more than compensating the night-time draining for some 12-14 d. In the saturated dynamic equilibrium situation of 16-18 May the maximum daytime protonospheric electron content (N_p) makes up some 20% of the total electron content (N_T) as opposed to only 11% on the day following the sudden commencement.

The first point to note from this study of N_p changes is that the regular diurnal variation, with early morning minimum

Fig. 1 Protonospheric content variations from 28 April 1976 to 21 May 1976. The dotted curve displays the mean diurnal variation for May 1976 recurring each day. Also plotted are the three-hourly values of the planetary geomagnetic index K_p .

and afternoon maximum, is essentially a quiet time phenomenon. When K_p values exceeding 3 are found over a period of several days the diurnal pattern of N_p becomes irregular with noiselike quasi-random fluctuations which tend to mask the diurnal component of the variation.

Enhanced geomagnetic activity accompanying a sudden commencement is associated with an increase in the daytime protonospheric content. This result is consistent with that reported by Poletti-Liuzzi *et al.*⁷. It is well known that ionospheric electron content can show a significant positive effect during daytime following sudden commencement. This increase is associated with the raising of the ionisation under the influence of the magnetospheric electric field penetrating to the mid-latitude ionosphere and also neutral winds, possibly reversed in direction and blowing equatorwards in response to enhanced temperatures in the auroral zone. It is thus to be expected that the increase in ionospheric plasma will be reflected in enhanced protonospheric content. An additional factor which may cause some enhancement in slant N_p is the expansion of the plasmasphere in the afternoon sector in response to increased magnetospheric convection.

The rapid depletion in N_p as the line of sight moves into the night side is consistent with the corresponding drop in ionospheric electron content and peak density reported by many workers. The main cause of this latter decrease is almost certainly linked to changes in thermospheric circulation reflected in an increased N_2/O ratio⁸, but the enhanced magnetospheric electric field probably plays a part in depressing the night-time ionisation and thus reducing the ionospheric electron content and hence protonospheric content. The additional factor which contributes to the lowering of the night-time N_p during the main phase of the storm is the contraction of the plasmapause radius caused by the convection electric field. For example, Park⁴ found that the plasmapause moved in to $L \approx 2.4$ several hours after local midnight during a storm in which K_p reached 7.

The slow refilling of the protonosphere after the storm depletion took ~ 14 d to reach saturation during the quiet conditions in May. The results of the whistler studies reported by Park⁴ indicate time constants to reach equilibrium ranging from ~ 1 d at $L=2.5$ to 8 d at $L=4$. The storm of 2 May 1976 with K_p maximising at 8+ was more intense than that discussed by Park so that the protonospheric depletion may have been more complete in our observations where the lowest N_p value ever found occurred, however, in terms of season and solar minimum epoch the data are comparable. Park's observations were interrupted by substorm activity after 8 d so that he was unable to study possible saturation beyond $L=4$. However, in

the present observations the period of quiet extends to ~ 17 d allowing complete equilibrium along the slant path to be reached after ~ 14 d when the plasmapause radius had extended to its furthest possible quiet time position. Murphy *et al.*⁵ calculated a post-storm saturation time for the H^+ tube content which was much greater than the experimental estimate of Park for $L=3$ at solar minimum—they reported a refilling time greater than 8 d at equinox.

After ~ 7 –8 d the N_p magnitudes and their diurnal variation become comparable with the monthly average values suggesting that the median protonospheric content measured by the ATS-6 experiment represents the integration over flux tubes up to $L \sim 4$.

We thank Professor Sir Granville Beynon, FRS, for his interest in planning ATS-6 observations, and Dr E. N. Bramley and Mr L. J. Martin (Appleton Laboratory) and Drs J. K. Hargreaves and S. Ganguly (University of Lancaster) for their cooperation in the ATS-6 project. Possible climatic and biological impact of nearby supernovae

OZONE plays a very important part in atmospheric radiative transfer. The absorption of the solar ultraviolet radiation by ozone is the dominant heating mechanism in the stratosphere. At thermal infrared wavelengths the main ozone contribution comes from the $9.6 \mu\text{m}$ band. Clark *et al.*¹ were unclear, however, whether the supernovae removal of ozone

from the atmosphere of the Earth would heat or cool the surface of the planet. There is evidence, reported here, which enables a more precise statement to be made of the effect upon the global Earth. The reduction in the concentration of ozone will cool the stratosphere, troposphere and surface layers of the Earth.

An estimate of the ozone effect upon the global temperature structure may be made through radiative equilibrium models in which the convective adjustment to the lapse rate is used to approximate the dynamical effects (see, for example, Manabe and Wetherald²). The atmospheric model is one dimensional and is allowed to reach an equilibrium structure with a time marching procedure. For the assumed atmospheric composition and initial temperature structure, the solar and thermal heating/cooling rates are calculated at each level and the net heating/cooling used to determine the temperature at each altitude at time $t + \Delta t$. If the computed temperature lapse rate exceeds the maximum assigned value of -6.5 K km^{-1} , then a convective adjustment occurs with a vertical energy flux sufficient to yield that pre-assigned maximum lapse rate. The time marching procedure is continued until equilibrium is reached at each level in the atmosphere, which is typically 300 d with a time step of 1 d. The final atmospheric structure is independent of the initial temperature profile.

Table 1 gives examples of predicted changes due to the reduction in ozone amount. The small difference in the exact magnitude of the change results from minor differences in the radiative schemes and cloud formulations used by the individual authors. In physical terms a reduction in ozone leads to a decrease in stratospheric solar absorption. The cooling of this region will reduce the downward longwave flux in the $9.6 \mu\text{m}$ band and therefore cool both the troposphere and surface. But the changes in the tropospheric temperatures will be much smaller than the stratospheric effects where ozone plays a dominant part (Table 2).

Table 1 Surface temperature changes due to reduced ozone

Ozone reduction (%)	Temperature change (K)	Ref.
25	-0.34	3
50	-0.3	5
	-0.4	4
100 (No ozone)	-0.5	5

The possible biological consequences of the reduction in atmospheric ozone through these supernovae events will be catastrophic for certain species, as DNA, which carries the genetic information of the cell, is easily modified by exposure to ultraviolet radiation. While living cells have a significant enzymatic capacity for repairing ultraviolet damage to their DNA, living things are in a delicate balance between the continual photochemical destruction of cellular components by solar radiation and their biological repair. If this balance is upset by exposure to increased amounts of ultraviolet radiation which would result from the supernovae events postulated by Clark *et al.*¹, the organism will be injured and may die.

The climatic implications of these supernovae events are also likely to be equally catastrophic. It is generally accepted that a reduction in global temperature of 1K is necessary to produce an ice age (see, for example, ref. 7), which would, of course, hide the larger changes that occur on a local scale. The calculations produced here may not suggest an immediate ice age would follow the complete destruction of atmospheric ozone; but these calculations have been performed with a simple model which does not include the feedbacks that may result from the dynamical

Table 2 Atmospheric temperature changes due to reduced ozone

Pressure (mbar)	Temperature change (K)		
	30% decrease ⁴	50% decrease ⁵	No ozone ⁵

1,000	-0.2	-0.3	-0.5

coupling between the stratosphere and troposphere. Some insight into these feedback mechanisms has been given by Bates⁸ who suggests the large changes in stratospheric temperature, such as those indicated in Table 2 due to the reduction in ozone amount, would greatly affect the stratospheric meteorology and in particular the static stability of this region. Furthermore, Bates⁸ shows that the ultra-long wave geopotential field in the troposphere is very sensitive to these stratospheric changes indicating a coupling between these atmospheric layers, and a further possible mechanism by which these stratospheric ozone changes would affect the terrestrial climate. There would seem to be little doubt the encounters with nearby supernovae, causing a major reduction in the atmospheric ozone content, would initiate an ice age as Clark *et al.*¹ postulated. This is a further example of an astronomical influence on the terrestrial environment.

Surface topography as a nonstationary random process

TOPOGRAPHY is often considered as a narrow bandwidth of features covering the form or shape of the surface. After detailed study of many measurements we consider that as well as the possibility of a dominant range of features there is always an underlying random structure where undulations in surface height continue over as broad a bandwidth as the surface size will allow. We consider this a result of many physical effects each confined to a specific waveband but no band being dominant. We invoke the central limit theorem and show through Gaussian statistics that the variance of the height distribution of such a structure is linearly related to the length of sample involved. In another form, the power spectral density, this relationship is shown to agree well with measurements of structures taken over many scales of size, and from throughout the physical universe.

Van Deusen¹ noted that the power spectral densities of a variety of natural and artificial surfaces fall off as the square of the angular frequency. It has since been observed particularly in the longer wavelength irregularities²⁻⁴ that many engineering surfaces exhibit similar spectra. Similarities in the structure of surfaces of such disparate scales of size suggest the existence of a common natural law underlying the phenomena. The specific form of the spectra further suggests that a sample of finite length taken from such a surface will never, however long, completely represent its properties. Real surfaces cannot

Fig. 1 The experimental points show the increase in normalised r.m.s. roughness ($\sigma/k^1, m^1$) with cut-off wavelength (λ_0, m) observed from two different topographies. The solid line represents the theory given by equation (1). ○, Grit blasted surface, $k(m)=1.7 \times 10^{-8}$ (ref. 7). △, Planed surface, $k(m)=4.4 \times 10^{-12}$ (ref. 2).

therefore be treated as stationary random processes, as has previously been supposed^{5,6}.

A further property of such a spectrum is that its energy increases rapidly with increasing wavelength. The area under the spectrum, which is the variance of the height distribution or, in engineer's terminology, the square of the r.m.s. roughness, is thus most heavily influenced by the longest wavelengths in the sample. This in turn suggests that the roughness must be related in some way to the length of sample or to the measured bandwidth, a hypothesis supported by experimental evidence^{2,7,8} (Fig. 1).

To form such a surface structure we postulate a process resulting from many random causes without preference for any one wavelength or waveband. From the central limit-theorem we would expect the amplitude distribution of a sample from such a process to be Gaussian. This is true even if the result of each individual effect forming the process is non-Gaussian. Furthermore, because the process cannot be confined to any one bandwidth, the variance of the Gaussian height distribution will be a function of the length of sample considered, or, equivalently, the bandwidth of features represented.

With a surface of a given finite area, if the heights are measured sufficiently closely together then an arbitrarily large sample can be obtained. Its extreme values, however, would not be very large and will therefore be a function not of the sample size, as for a discrete normal variate, but of the area over which the sample was taken. This is because in the physical world we do not expect things to vary by vast amounts in short periods or distances: a consequence, broadly speaking, of the energy necessary to create large changes in values. Large changes in surface height on Gaussian surfaces are possible but they tend to occur over large distances. This argument suggests that in physical situations a Gaussian stationary process is in fact a contradiction in terms.

Suppose the standard deviation σ of the height distribution is a function of the length of sample L , that is, $\sigma = f(L)$. To investigate the effects of increasing sample length on r.m.s. roughness we will consider consecutive lengths L_1 and L_2 . Wiener⁹, considering the analogous problem of the wandering of a particle in non-overlapping intervals of time, showed that if the two distributions governing the extent of wandering were independent and Gaussian, then the combined distribution is also Gaussian. Thus giving the standard result of the addition theorem that the variances add to form the variance

of the new distribution. The interesting aspect of this result is that in our case, where the standard deviation is a function of sample length then because

$$\sigma^2 = \sigma_1^2 + \sigma_2^2$$

we can write,

$$f^2(L_1 + L_2) = f^2(L_1) + f^2(L_2)$$

and the only function $f(L)$ which holds for the above equation is a linear one,

$$\sigma^2 \propto L$$

The relationship depends on the independence argued between samples, thus with machined surfaces it is restricted to a certain range of features. In general this range is most evident over the spatially longer features of the topography, the smaller features being dominated by the machining marks; however, many natural surfaces have no such restrictions. In such cases the process involved corresponds to the non-stationary Wiener-Levy process¹⁰, of which the best-known example is Brownian motion. Such a process is continuous but nowhere differentiable, confirming the view⁵ that slopes, curvatures and densities of maxima and minima are not, as was formerly widely believed, intrinsic properties of a surface.

This relationship can be expressed in a spectral form, as the effective high-pass cutoff wavelength λ_0 of a sample must be proportional to its length, that is,

$$\sigma^2 = k\lambda_0 = 2\pi k/\omega_0 \quad (1)$$

where ω_0 is the corresponding angular frequency and k the constant of proportionality, a result confirmed by experiment (Fig. 1). But the area under the power spectral density curve $G(\omega)$ is also the variance of the height distribution:

$$\sigma^2 = \int_{\omega_0}^{\infty} G(\omega) d\omega$$

Combining the above two equations, and assuming

Fig. 2 Variation of normalised power spectral density ($G(1/\lambda)/k, m^2$) with wavelength (λ, m). The graph shows that many different surface topographies existing in the physical universe have a similar form of power spectrum. Note that the spectra available cover almost eight decades of surface wavelength and throughout this range the r.m.s. power increases, to a good approximation, as the square of the wavelength (solid line, equation (2)).

$$\lim_{\omega \rightarrow \infty} G(\omega) = 0$$

which is expected with physical data, then

$$G(\omega) = 2\pi k/\omega^2 = (k/2\pi)\lambda^2 \\ \text{or } G(1/\lambda) = k\lambda^2 \quad (2)$$

in agreement with experiment (Figure 2).

We call k the 'topothesy' of the surface (τοποθεσία, a description of a place or region¹⁷). Its value uniquely defines the statistical geometry of the random components of an isotropic surface for any given range of wavelengths. The topothesy has units of length. It seems able to characterise successfully and completely, examples of surface structures of a wide range of sizes (Fig. 2) drawn from throughout the physical universe.

Isotope separation by 'Taylor diffusion'

THE axial dispersion of injected diffusible matter in a fluid flowing in steady laminar regime through a tube has been described by Taylor. On this principle, a simple technical device enabling isotopic separation can be constructed. The separation factor for light stable isotopes is higher than that reached by standard methods; solar energy can be used as an energy source for its functioning.

Taylor^{1,2} and later Aris³ have shown that when a soluble substance is introduced into a fluid flowing through a tube in laminar regime, it spreads out under the combined action of molecular diffusion and the variation of velocity over cross-section. The axial dispersion can be characterised by a virtual coefficient of diffusion (K) which is given by

$$K = (a^2 \bar{u}^2 / 48D) + D \quad (1)$$

if the following condition holds

$$(4L/a) \gg (\bar{u}a/D) \quad (2)$$

D is the coefficient of molecular diffusion of the soluble substance assumed to be independent of its concentration; a is the radius of

the tube, L the distance between the point of introduction and measurement and \bar{u} the mean axial velocity of convection.

If the origin of the coordinates ($z = 0$) is chosen at the point where the substance is injected instantaneously, its axial distribution can be described by the Gaussian curve

$$C(z, t) = \frac{1}{2}(\pi K t)^{-1/2} \exp[-(z - \bar{u}t)^2 / 4Kt] \quad (3)$$

which is the solution of the diffusion equation

$$\frac{\partial C}{\partial t} = K \frac{\partial^2 C}{\partial z^2} - \bar{u} \frac{\partial C}{\partial z} \quad (4)$$

with $C(z, t = 0) = \delta(z)$ as initial condition.

Taylor diffusion has been considered as one of the mechanisms of gas mixing in the human lung. Our previous work on gas transport in the bronchial ducts⁴ has led to a straightforward application of Taylor diffusion to separate isotopes⁵.

Each element of separation (Fig. 1) is essentially formed by a simple tube of length L and circular cross-section of radius a , through which a carrier fluid flows in steady laminar regime. At one end of the tube ($z = 0$), pulses of isotopic mixture are injected periodically with a frequency f . The concentration of a single pulse is given by equations (1) and (3), where D is the molecular diffusion coefficient of each isotopic component in the carrier fluid. Concentration curves must crossover and these intersection points define alternate zones in the tube which are enriched in one or other of the isotopes (bottom of Fig. 1). Heavy isotopes spread more than light ones.

If a valve system is used at point $z = L$, enabling the alternate communication between the principal duct and each of the secondary ducts, and if the valve switch times correspond to crossover concentration points, then each secondary tube will be enriched in one particular isotope.

The separation factor α is given by the classical formula⁶

$$\alpha = \frac{n_{1S}n_{2I}}{n_{1I}n_{2S}} \quad (5)$$

In our case n_{1S} and n_{2I} are the number of molecules of isotope 1 and 2 in the upper (S) and lower (I) secondary ducts respectively (Fig. 1). (We assume $n_{1S} > n_{1I}$.)

In order to produce a fast axial dispersion, we chose parametrical values such that

$$\frac{a^2 \bar{u}^2}{48D} \gg D \quad (6)$$

which, together with condition (2) is consistent with Reynolds numbers ensuring laminar flow. If we call K_1 and K_2 the dispersion coefficients given by equation (1) for isotope 1 and 2 we have

$$\frac{K_2}{K_1} = \frac{D_1}{D_2} \quad (7)$$

Where D_1 and D_2 are the molecular diffusion coefficients of isotopes 1 and 2 in the carrier fluid.

Let m_1 , m_2 and m_0 be the molecular weights of isotope 1, 2 and

Fig. 1 Isotope separation element: 1, main duct; 2, inflow of carrier fluid; 3, isotopic mixture injection point; 4, injection valve; 5, inflow of isotopic mixture; 6, outflow valve; 7, 8, outflow or secondary ducts; 9, 10, separators of isotopic mixture and carrier fluid; 11, 12, outflow of carrier gas; 13, 14, outflow of isotopic mixture. The concentration of each isotope after $t = L/\bar{u}$ after first injection and expressed as a fraction of the injected concentration. Shaded zones correspond to zones enriched in light isotope.

the carrier fluid respectively. From the Chapman-Enskog classical equation, one can show that

$$K_2/K_1 = (m_2/m_1)^{1/2} [(m_0 + m_1)/(m_0 + m_2)]^{1/2} \quad (8)$$

if $m_2 > m_1$. If $m_1 \approx m_2$, we can write

$$K_2/K_1 = 1 + \varepsilon; \quad \varepsilon \ll 1 \quad (9)$$

When inequality 2 holds, equation (3) can be approximated by a Gaussian distribution and the separation factor is then given by

$$\alpha = 1 + \varepsilon \{ (2\pi e)^{1/2} \operatorname{erf}(1/\sqrt{2}) [1 - \operatorname{erf}(1/\sqrt{2})] \}^{-1} \quad (10)$$

or

$$\alpha = 1 + 1.12\varepsilon \quad (11)$$

Among the different methods of isotopic separation, mass diffusion developed by Hertz^{7,8} also makes use of an auxiliary gas. Later, Maier⁹ used elements consisting of concentric columns separated by a barrier and a feed gas was injected into the innermost column. The faster molecular diffusion of the lighter isotope in the feed gas enables separation.

Both in mass diffusion and in our method, almost all the energy used in the process is related to the separation of the isotopic mixture and the auxiliary fluid. Indeed, in our method, the energy consumption associated with the pipe flow viscous losses is very small. The minimum work required to separate m_1 moles of isotopic mixture and m_2 moles of auxiliary fluid is given by

$$W = RT \left(m_1 \ln \frac{m_1}{m_1 + m_2} + m_2 \ln \frac{m_2}{m_1 + m_2} \right) \quad (12)$$

Where T is the absolute temperature and R the gas constant⁶. However, the proposed method presents three important advantages over mass diffusion: firstly, the simplicity of the element of separation, which is basically constituted by a simple tube; secondly, fluids in their liquid phase can be used, which leads to much smaller plants, and finally, the possibility of having a higher

separation factor. Indeed, in mass diffusion plants, it is recommended that an auxiliary gas and isotopic mixture of close molecular weights be used to avoid slow molecular diffusion⁶. In the present method, because of the inverse relationship between axial dispersion and molecular diffusion (equation (1)), a heavy carrier gas produces a fast dispersion which results also in a higher separation factor. It can then approach the limiting value of $1 + 1.12(m_2/m_1)^{1/2}$.

We have represented infinitesimally small isotopic injections by Dirac functions, in order to get analytical expressions for the separation factor. But, if the mean fractional concentration of the injected mixture in the principal tube is equal to 0.1, numerical integration shows that the separation factor should be multiplied by 0.965.

In Table 1 we present separation factors for isotopes $C^{12}-C^{13}$ given by Benedict and Pigford⁶ for different methods of isotopic separation as well as for the present one. These values are theoretical and can be much smaller in practice. The experimental factor for gaseous diffusion, for example, is about half the theoretical one. Our experimental evidence is sufficiently conclusive for us to believe that in the present method, the experimental separation factor will be much closer to the theoretical one. Indeed, our experiments have shown¹⁰ that the concentration curves, which are not disturbed by the movement of valves, fit equation (3) very well.

Table 1 Comparison of α for separation of C^{12} and C^{13} using different methods

Separation method	Working substances	α
Chemical exchange	HCN-CN ⁻	1.013
Distillation	CO	1.010
Gaseous diffusion	CH ₄	1.030
Mass diffusion	CH ₄ -H ₂ O	1.016
Thermal diffusion	CH ₄	1.0026
Gas centrifuge	CH ₄	1.009
Present method (with the mean isotope concentration equal to 10%)	CH ₄ -C ₄ F ₁₀	1.031

The separation of stable light isotopes constitutes probably the most interesting short-term application of our method. The energy cost of separation constitutes only a few per cent of the present cost of stable isotopes. The possible application for enriching uranium in isotope 235 is related to the availability of very heavy molecules. Using $N(C_4F_9)_3$ as carrier fluid, this would lead to a separation factor of 1.0031. The construction of an experimental device for separating uranium isotopes is now under study.

I thank Professors A. Jaumotte and J. E. Dumont, Drs J. W. Turner and I. Paiva-Veretennicoff for help and advice, Professor J. Jeener for stimulating discussions, Mrs D. Leemans for typing the manuscript and Mr and Mrs Pengally for revising the English text. This work was supported by the Conseil National de la Politique Scientifique.

First proof of structure of a C_{28} -pentacyclic triterpane in petroleum

DURING the past decade, C_{27} , C_{29} , C_{30} , and C_{31} modified pentacyclic triterpane hydrocarbons, mainly hopanes, have been discovered in fossil fuels¹⁻⁴. Besides their fundamental importance as diagenetic products from the conversion of living organisms to hydrocarbon deposits in nature, the interpretation of their structure in terms of precursor-product relationships promises to be useful for problems of petroleum exploration^{5,6}. The reported presence of 'degraded triterpanes containing 27 and 29 but not 28 carbon atoms'² has mechanistically been rationalised² in analogy to the observed absence of C_{17} -isoprenoid hydrocarbons in fossil fuels because of the unlikelyhood of cleavage of two carbon-carbon bonds located at the same carbon atom (C-22) of the hopane side chain. We determine here the structure of a C_{28} member of the hopane family, 17 α (H), 18 α (H), 21 β (H)-28,30-bisnorhopane (Fig. 1) and its enormous natural abundance (26 p.p.m. of rock) in the Monterey shale, offshore Santa Barbara, California.

After isolation of saturates⁷ from the shale extract, a concentrate containing 50% of C_{28} -triterpane was isolated by preparative gas chromatography⁷. Further purification on acidic alumina I (ref. 8) revealed the presence of at least two components in the ratio of 3 : 1 and led to the isolation of $C_{28}H_{48}$ -triterpane-I (Fig. 1), the predominating component, in crystalline form (melting point 150–152 °C), by slow evaporation of a concentrated hexane solution.

Proof of structure of $C_{28}H_{48}$ -triterpane-I as being a bisnorhopane with methyl groups missing at C-18 and C-22 and 17 α (H), 21 β (H) stereochemistry, being 17 α (H)-28-noradientane, was obtained as follows: (1) mass spectrometry: 70 eV, m/e (relative intensity) 384 (95, M⁺), 369 (12, M-CH₃), 355 (10, M-C₂H₅), 191 (100, rings A+B), 177 (20), 163 (30, rings D+E), 149 (15). The observed ratio of intensities at m/e 191 to that at 163 is consistent with 17 α (H), 21 β (H) stereochemistry³. The m/e 355 fragment signals an intact ethyl side chain. The remaining methyl deficiency must, therefore, be one of the angular methyl groups on the triterpane nucleus. The high

abundance of m/e 191 indicates the A and B portion of the hopane ring system intact. The facile cleavage of C-8/C-14 bond to produce the two major fragments at m/e 191 and 163 indicates the presence of 8 β - and 14 α -methyl groups. Thus, the methyl group must have been lost from C-18. The mass spectral evidence by itself, however, does not permit clear distinction from an alternate structure, namely, 28,30-bisnorlupane. Elimination of the latter and confirmation of the structure of $C_{28}H_{48}$ -triterpane-I (Fig. 1) was achieved by X-ray crystallography.

(2) X-ray crystallography: the compound is orthorhombic, space group P2₁2₁2₁, with $Z = 4$. The cell parameters are: $a = 11.26$ Å, $b = 7.36$ Å, $c = 28.38$ Å. 3,090 Reflections were measured on an automatic diffractometer of which 2,242 were considered to be observed. The structure was solved by direct methods, and the data were refined to $R = 0.068$ by block-diagonal least-squares refinement of structure factors. The mean bond distance over 32 values is 1.536 (21) Å; and all distances are within the 2 σ limit except the C-8/C-14 distance, which is 1.600 Å, analogous to 1.622 Å in 17 α (H)-adientane¹⁰, explaining the observed facile cleavage of this bond by mass spectrometry.

(3) NMR: 360 MHz, (CDCl₃) δ 0.793 (3,s,4 β -CH₃), 0.834 (3,s,4 α -CH₃), 0.843 (3,s,10 β -CH₃), 0.886 (3,t, $\delta = 7$ Hz, 22-CH₃), 0.899 (3,s,14 α -CH₃), 0.937 (3,s,8 β -CH₃); the chemical shifts of the 4 β , 4 α , and 10 β -methyl group protons are equivalent to those shifts for 17 α (H)-hopane [(CDCl₃) δ 0.80 (4 β), 0.83 (4 α), 0.85 (10 β)] (ref. 11), and the 8 β -methyl protons are only slightly shifted from those of 17 α (H)-hopane [δ 0.96 (8 β)] (ref. 11) confirming the natural carbon skeleton for the ring A-B portion of $C_{28}H_{48}$ -triterpane-I. The relatively large upfield shift for the 14 α -methyl protons from 1.00 p.p.m. in 17 α (H)-hopane¹¹ to 0.899 p.p.m. in $C_{28}H_{48}$ -triterpane-I is consistent with a relief of steric interaction by removal of the 18 α -methyl group, whose signal is absent in $C_{28}H_{48}$ -triterpane-I [0.91 p.p.m. in 17 α (H)-hopane]¹¹.

The particular C_{28} -triterpane reported here seems to be either absent, or present only in traces, in most fossil fuel samples¹⁻⁴. However, it is present in many California crudes⁵ and occurs with abundance in the nearby Monterey shale and presumably also in large abundance in a crude form from the Northern Volga Ural (Siva) Region (USSR)¹². This points toward some unique diagenetic pathway. Present speculation centres on adipedatol¹³, a fern triterpenoid of the 30-norhopane type possessing a hemiacetal linkage between C-22 and C-28. Hydrolysis would yield a CH₂OH-group at C-18 whose oxidation to the corresponding carboxylic acid and subsequent decarboxylation, all accepted geochemical processes¹⁴, would yield the identified hydrocarbon (Fig. 1).

An alternate precursor-product relationship can be visualised starting with adiantone (C_{29}). The latter was postulated¹⁵ to be the precursor for certain partially aromatised hopanes in fossil fuels of proven structure possessing the ethyl side chain in ring E, analogous to $C_{28}H_{48}$ -triterpane-I. The progressive aromatisation required is assumed to begin in ring D. Thus, introduction of the first double bond by reduction of adiantone, dehydration, and shift of the double bond into ring D into the most stable 13(18) position¹⁶ under strongly acidic conditions must result in elimination of the methyl group at C-18. Hydrogenation at this point, parallel or in lieu of aromatisation due to the particular geochemical environment, would yield our $C_{28}H_{48}$ -triterpane-I. Similarly 21-hydroxyadientone¹⁷, a fern constituent, could give rise to our C_{28} -triterpane through formation of a conjugated diene, accompanied by loss of the methyl group at C-18 and subsequent hydrogenation.

Finally, to explain the unusual abundance of this bisnorhopane in selected cases (Monterey, Siva), there is the remote possibility of a molecular sieve effect in nature, that is enrichment by molecular size due to pore size of the particular inorganic matrix present. Current investigations deal with the structure of the second $C_{28}H_{48}$ -triterpane isomer present in minor quantity.

Fig. 1 Structure of $C_{28}H_{48}$ -triterpane-I. a, 17 α (H), 18 α (H), 21 β (H)-28,30-bisnorhopane; b, stereoscopic view drawn by ORTEP⁹, vibration ellipsoids scaled to 50% probability.

Strontium isotope evidence for petrogenesis of Mexican andesites

THE Mexican volcanic belt (MVB) consists of several inactive and active volcanoes¹ (Fig. 1). The active volcanoes include Colima^{1,2} and Ceboruco³ near the Pacific coast, Popocatepetl and Iztaccihuatl in central Mexico, and San Martin⁴ close to the Caribbean coast. The MVB rests on continental crust approximately 40 km thick^{5,6}, and is associated with subduction of the Cocos plate below central Mexico^{7,8}. The link between plate subduction and the disposition of the MVB is not simple since the latter makes an angle of about 20° with the Middle America Trench⁹. This complexity might be related to the structure of the continental crust⁵, or to a combination of subduction and extensional processes⁴. The most prominent products of volcanism of the MVB are the large composite volcanoes built up from successive eruptions of intermediate lavas and pyroclastic rocks^{3,8}. The lavas of the active volcanoes shown in Fig. 1 are dominantly calc-alkaline andesite and dacite^{3,8–10}. In contrast, the easternmost active volcano, San Martin, is built from lavas of a picritic basalt-basanitoid-alkali basalt-hawaiite association^{4,11,12}. This volcanic area occurs at a change in direction of the MVB and might therefore be linked with extension or fracturing associated with the destructive margin setting of the MVB (ref. 4). Here we report new Sr isotope data for lavas from Ceboruco, Colima, and San Martin. These data, and published Sr isotope data for Cainozoic volcanics from central Mexico¹³ constitute evidence for petrogenesis of Mexican volcanic rocks.

The only published Sr isotope data for Mexican lavas are from rocks of Miocene–Recent age from the area

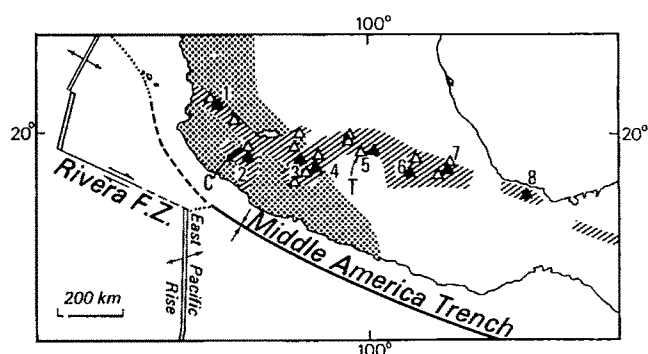

Fig. 1 Volcanoes and plate tectonics of Central Mexico. The two Cainozoic volcanic provinces are shown: the stippled area is the Cordilleran Province and the diagonal shading is the Mexican volcanic belt³. Δ , Inactive composite volcanoes including C, Nevado de Colima and T, Nevado de Toluca. \blacktriangle , Recently active volcanoes numbered: 1, Ceboruco; 2, Colima; 3, Paricutin; 4, Jorullo; 5, Xitli; 6, Popocatepetl; 7, Orizaba; 8, San Martin.

around the inactive volcano, Nevado de Toluca^{13,14} (Fig. 1). Whitford and Bloomfield¹³ have obtained Sr isotope ratios in the range 0.7032–0.7045 for 30 samples of lavas from the Toluca area. There is no overall correlation between $^{87}\text{Rb}/^{86}\text{Sr}$ and $^{87}\text{Sr}/^{86}\text{Sr}$, but 10 samples from the immediate vicinity of the volcano show a significant positive correlation indicating an apparent age of 430 ± 97 Myr (ref. 13, p. 211). Whitford and Bloomfield argue that the relatively low $^{87}\text{Sr}/^{86}\text{Sr}$ ratios suggest an ultimate origin in the mantle (ref. 13, p. 212).

We have determined Sr isotope data for 16 Pliocene–Recent lavas from Ceboruco, the Colima area and San Martin. Sr isotope ratios were determined on a VG-Micromass 30 mass spectrometer using chemical and mass-spectrometric techniques described elsewhere¹⁵. Measurements of the Eimer and Amend standard SrCO_3 carried out during this work yield an overall mean of 0.70814 ± 1 . Rb/Sr isotope ratios were determined by a precise X-ray fluorescence technique¹⁶. The Sr isotope ratios and related analytical data for the Mexican lavas are presented in Table 1. Because the analysed samples are all geologically very young (< 1 Myr), the $^{87}\text{Sr}/^{86}\text{Sr}$ ratios presented in Table 1 are taken as initial ratios. These data are shown as a plot of $^{87}\text{Rb}/^{86}\text{Sr}$ against $^{87}\text{Sr}/^{86}\text{Sr}$ in Fig. 2.

Figure 2 shows that the Sr isotope compositions of samples from the Colima area and from San Martin show slight but significant internal variation within the range

0.7036–0.7040 but lie entirely within the range of data for the Toluca area reported by Whitford and Bloomfield (0.7032–0.7045, ref. 13). In contrast, the Ceboruco samples show virtually no significant variation and have ⁸⁷Sr/⁸⁶Sr ratios higher than any data from Colima or San Martin with an average of 0.7042. None of the new sets of data for individual volcanoes show significant correlation of ⁸⁷Sr/⁸⁶Sr with Rb⁸⁷/Sr⁸⁶ (see ref. 17). These data enable us to comment as follows on the petrogenesis of Mexican volcanics.

Values of ⁸⁷Sr/⁸⁶Sr for all analyses of andesitic volcanics fall into the range reported for intermediate lavas from Central America^{18,19}, and for lavas from volcanic arcs where sialic crust is absent^{20–22}. The low Sr isotope ratios for these andesites, commonly in the range 0.7035–0.7040, suggest that sialic contribution to their origin is insignificant.

The mean Sr isotope ratio of 0.7042 of the Ceboruco lavas is significantly higher than that for most of the other samples plotted in Fig. 2, although slightly lower than most continental andesites from South America^{23,24}. These higher ratios could be accounted for by slight contamination of Ceboruco lavas with crustal Sr (compare ref. 23). Ceboruco is also anomalous in showing a high rate of increase in K₂O relative to SiO₂ in comparison with other volcanics from the MVB³. In view of the internal consistency of the Ceboruco Sr isotope ratios, and the similarity of absolute Sr concentrations in Ceboruco lavas to other Mexican andesites (Table 1), it is possible that the higher Sr isotope ratios reflect the Sr isotope composition of the mantle below the volcano. The Sr isotope data therefore suggest a small degree of mantle Sr isotope heterogeneity below the western part of the MVB.

The Sr isotope ratios of the basanites and alkali basalts from San Martin fall into the general range reported for alkali basalts from elsewhere^{25–27}. We suggest that the similarity of Sr isotope values for San Martin basalts with most Mexican andesites indicates a common mantle source.

The Sr isotope data are furthermore consistent with experimental evidence that undersaturated basalt and over-saturated andesite might both be contrasted products of partial melting of mantle peridotite under different conditions of pressure, temperature and activity of water in the coexisting volatile phase²⁸.

Rock samples were collected from Colima during a visit sponsored by Earthwatch (Educational Expeditions International) and the Centre for Field Research (Belmont, Massachusetts). We thank the expedition participants for help in collecting samples and J. S. Vizcaino for much help on Colima. The isotope work at Oxford is supported by NERC.

Rapakivi granite, anorthosite and charnockitic plutonism

THE close association of massive anorthosite and charnockitic granitic rocks is well documented¹. Rare earth element (REE) investigations²⁻⁴ have indicated that the massive charnockite (mangerite) associated with anorthosite is not comagmatic with it but represents a distinct magma fraction. Bridgwater *et al.*⁵ describe a charnockitic mantle around a plutonic suite of norites, monzonites and rapakivi granites from the Kap Farvel district of south Greenland which they consider to represent a parallel situation to the anorthosite-mangerite association. They believe contact metamorphic processes accompanied by anatexis produced the charnockitic phases. The charnockites are, therefore, dependent on the associated igneous suites but are not comagmatic with them. Duchesne *et al.*⁷ have investigated the REE content of monzonitic rocks considered consanguineous with the anorthosites of the South Rogaland district of southern Norway. The absence of any Eu anomaly in the monzonitic rocks, as compared with the marked positive Eu anomaly found for the anorthosites, places severe constraints on any postulated common parent magma for this rock association. A magma produced by partial fusion of upper mantle Kaersutite has been suggested⁷. A link between anorthosite and rapakivi granite⁸ has been proposed, rapakivi granite being a high level crystallisation related to and contemporaneous with anorthosite emplacement at greater depth. From their study of the Pikes Peak Batholith, Colorado, Barker *et al.*⁸ proposed a composite model for the origin of the rock spectrum gabbro-anorthosite-syenite-granite (including rapakivi granite). Convecting, mantle-derived, alkaline olivine basalt magma is believed to produce a quartz-syenitic magma from K₂O-poor lower crustal rocks which in turn reacts with the granodioritic to granitic rocks of higher crustal levels to produce biotite and biotite-hornblende granites. Anorthosite is a precipitate phase from intermediate liquids. Our results from an REE investigation of plutonic charnockitic rocks and associated granites from south-west Sweden suggest that rapakivi granite may be associated with the charnockites satellitic to anorthosite rather than with anorthosite itself.

The southern parts of the south-west Swedish gneiss belt have much in common with the south Norwegian anorthosite province although no massive anorthosite has been located in the Swedish area. An intrusive, compound, plutonic association, the Charnokite-Granite Association (C.G.A.), which includes both charnockitic and non-charnockitic components, outcrops in the Varberg area of south-west Sweden⁹. This complex was initiated, mobilised and emplaced during a metamorphism which produced *in situ* charnockitisation within the country rock sequences; meta-arkosic gneisses and a more varied layered sequence with a significant basic metavolcanic com-

Fig. 1 Chondrite-normalised REE distribution curves. 1. Torpa granite of the C.G.A. 2. Charnockitic members of the C.G.A. 3. Charnockitised granite gneiss, Varberg Formation. 4. Charnokitic quartzofeldspathic granulite, Varberg Formation. Data of Table 1 normalised against Leedey L6 chondrite.

ponent. The admixture of charnockitic and non-charnockitic elements in the C.G.A. is interpreted on the basis of an internal differentiation during emplacement, controlled by H₂O aggregation. The ultimate result of the segregation process was the separation of a differentially mobile, relatively 'wet', granite fraction from a comparatively sluggish, 'dry', intermediate residuum. The latter crystallised as massive charnockite without having travelled far from the site of original anatexic melt generation. By virtue of its differing physicochemical properties, however, the granite differentiate was able to rise further and could separate from its cogenetic charnockite associates. In the Varberg occurrence, however, the link with the charnockites was never completely severed. The advancing head of the granite (the Torpa granite) passed from the granulite sequence, thought to represent reworked basement, to an overlying sequence of layered metasedimentary cover rocks where it spread laterally to crystallise as a series of subconformable sheets⁹. This effectively halted further separation.

The rare earths La, Ce, Nd, Sm, Eu, Tb, Yb and Lu have been determined by instrumental neutron activation analysis for the charnockitic and non-charnockitic elements of the C.G.A. and quartzofeldspathic components of the country rocks (Table 1). The chondrite-normalised averaged distribution curves are presented in Fig. 1. If the C.G.A. is an anatexic derivative from rocks similar to its country rocks, as is believed, a significant accumulation of rare earth elements is involved. All rock groupings show strong differentiation, generally with fairly marked inflexion. The C.G.A. charnockitic rock pattern is similar to that obtained for the Quebec mangerite by Philpotts *et al.* but differs from that found for the massive mangerite of the Lofoten-Vesterdaalen province by Green *et al.*⁴ in that there is no sign of the development of a positive Eu anomaly. It is, however, similar to the pattern for the Moskensøy gneisses marginal to the Lofoten anorthosite⁴. The change from charnockite to non-charnockite within the C.G.A. is marked by concentration of the light rare earth elements La, Ce and Nd, increase in total REE and increase in the differentiation index La/Yb from 12 to 27. The non-charnockitic Torpa granite is further distinguished by the development of a negative Eu anomaly.

In Fig. 2 the chondrite-normalised REE distribution plot for the Torpa granite is compared with some average granite

Table 1 REE concentrations in charnockitic and non-charnockitic quartzofeldspathic rocks from the Varberg area (in p.p.m.)

	La	Ce	Nd	Sm	Eu	Tb	Yb	Lu
1	152	334	106	17.0	3.7	2.0	5.7	0.9
2	77.2	155	70.3	18.4	3.0	1.9	6.5	1.0
3	49.7	85.6	36.3	6.8	1.3	0.9	3.3	0.5
4	22.7	49.5	15.0	5.1	1.3	0.5	3.3	0.4

1. Torpa granite (non-charnockitic) of the C.G.A. (three analyses).
 2. Charnockitic phases of C.G.A. (nine analyses).
 3. Granite-gneiss (meta-arkose) (four analyses).
 4. Quartzofeldspathic granulite (two analyses).

Fig. 2 Comparison of granitic REE chondrite-normalised distribution plots. 1. Torpa granite of C.G.A. 2. Finnish rapakivi granites (after Koljonen *et al.*⁸). 3. 70% SiO₂ granite composite (after Haskin *et al.*⁹). 4. Svecofennian granite (after Koljonen *et al.*⁸).

plots^{10,11}. In both total REE and differentiation style the Torpa granite is strikingly similar to the Finnish rapakivi granites, as reported by Koljonen and Rosenberg¹⁰ and Vormia¹². Identity is marred only by the more pronounced Eu anomaly shown by the Finnish rocks. Both the Swedish and Finnish rocks have REE chemistries which distinguish them from granites of comparable major element composition.

The similar and distinctive REE characteristics of the Finnish rapakivi granites and the Torpa granite of south-west Sweden suggest that they may be similar rocks with a comparable petrogenesis, that is, the Torpa granite is of Finnish rapakivi type. The distinctive mantled megacryst feldspar rapakivi texture occurs, albeit sparingly, within the Torpa granite mass. Although variation in major element chemistry is considerable within rocks recognised as belonging to the rapakivi suite, the SiO₂ range is 64–72%, K₂O is high and MgO always very low⁸. The average SiO₂ for the Torpa granite is 70.7%, K₂O is 5.58% and MgO is 0.52%. The corresponding figures for a rapakivi granite from Satakunta, Finland¹⁰, are: SiO₂ = 68.16%, K₂O = 6.89% and MgO = 0.50%. In contrast, the average values for the charnockites of the C.G.A. are: SiO₂ = 62.73%, K₂O = 4.61% and MgO = 1.51%.

In the Varberg occurrence the relationship of the rapakivi type Torpa granite to the charnockitic plutonism is direct and clearly observable in the field. It is possible that a similar relationship is preserved in the border zones of the large Wiborg rapakivi pluton of south Finland where the red rapakivi granite is reported to grade to dark green rocks akin to mangerite found associated with Precambrian anorthosites⁸. In many cases, however, the granite may have separated entirely from the charnockitic source areas.

On the basis of this study it is proposed that, if a connection exists between rapakivi granite and massive anorthosite, it is indirect. The emplacement of anorthosite in a high-grade crustal environment induces charnockitic recrystallisation and anatectic plutonism in the adjacent country rocks. In some cases, the products of this plutonic activity may differentiate to produce a mobile granitic fraction of rapakivi type which may rise to crystallise at higher crustal levels, sometimes completely dissociated from its source. Rapakivi granite is a product of charnockitic plutonism which in some cases is triggered by anorthositic emplacement.

In the Varberg area no anorthosite is exposed but may exist at unexposed levels. The accession of hot mantle material other

than anorthosite to the deeper crustal levels might be expected to engender charnockite-rapakivi plutonism in a similar manner. There is evidence in the south-west Swedish province of significant ultrabasic and basic magmatic activity contemporaneous with the charnockitisation.

Apomixis may be widespread among trees of the climax rain forest

THE exceptional species diversity of tropical rain forests is well known; of these the lowland forests of the Malay Peninsula are among the richest¹. This, and the size of the trees, pose obvious difficulties for the maintenance of panmixis, and tempt speculation on the processes by which such diversity has evolved and may now be favoured. Fedorov² suggested that natural selection is low and self-pollination prevalent, favouring random genetic drift. Prevalence of random drift, or apomixis—agamosperry—would contradict Ashton's³ view that, given a stable environment, evolution proceeds through ecotypic differentiation while diversity accrues through ever increasing niche specialisation; for this view to be correct, maintenance of genetic variability within breeding groups would be essential. Solid evidence has been meagre but there is evidence⁴ that genetic polymorphism, and hence heterozygosity, is common in the emergent tree *Shorea leprosula* Miq., and *Xerospermum intermedium* Radlk., an understorey species. The pattern of spatial variation is consistent with the view that these species are outbreeders in which predominantly short-range pollen and fruit dispersal are accompanied by short-range heterogeneity in gene frequencies. However, both are common trees with minimal spatial isolation. We now report the occurrence of apomixis in some other rain forest trees.

Apomixis through adventive polyembryony is well known in cultivated mangoes⁵ whose wild relatives are main canopy trees of the mature phase rain forest, and in cultivated *Citrus*, *Eugenia*, *Garcinia mangostana* Roxb. and *Lansium*^{6–8}, fruit trees which originated from its understorey. We do not know whether such patterns of embryogenesis have arisen after cultivation. Apomixis can also be inferred from triploidy in root-tip squashes derived from several seedlings originating from a single tree of the dipterocarp *Hopea latifolia* Sym. ($2n = 3x = 21$) (misidentified at the time as *H. beccariana*) in Semengoh Forest, Sarawak, West Borneo⁹. A.K. found triploidy also in *Hopea subulata* Sym. ($2n = 3x = 21$), where she also observed that some, or in certain cases all, the embryo sacs abort well before anthesis.

Apomixis can now be demonstrated in the Malayan

emergent dipterocarp *Shorea ovalis* (Korth.) Bl. ssp. *sericea* (Dyer) Ashton, in which, as noted previously, experimental selfings and crossings each lead to similar and relatively high levels of fruit set, and in *S. agami* Wood ex Ashton. *S. leprosula*, with which they grow in mixture, is a diploid with a high level of self-incompatibility in which embryo sac development is of the *Polygonum* type, and embryogenesis is normal. In *S. ovalis* we found that a suite of at least five proembryos develops at the micropylar end from the nucellus; these are therefore almost certainly genetically identical to the parent. Frequently only two seedlings germinate from a single seed and this suggests that only a small proportion of proembryos reach maturity. *S. agami* manifests essentially the same pattern although fewer proembryos seem to be formed. *S. ovalis* examined by us are tetraploid ($2n = 4x = 28$), with meiotic irregularities in the form of univalent and multivalent chromosome associations^{9,10}. The low level of genetic polymorphism reported earlier in this species⁴ may thus be an artefact occasioned by polyploidy.

Table 1 shows that at least one of a syndrome of characters often associated with apomixis, including the occurrence of multiple seedlings in normally single-seeded fruit, high levels of putative self-compatibility, low pollen germinability, irregular meiosis and polyploidy, may occur in rain forest dipterocarps of both canopy and understorey.

Maury¹¹ observed multiple seedlings in, among others, two close relatives of *S. leprosula*: *S. parvifolia* Dyer ($2x = 14$), in which we failed to find any multiple seedlings in

more than 300 seeds examined from another population and *S. argentifolia* Sym. ex Wood ($2x = 14$), in which we found a low percentage. She believed, though on inferential evidence only, that *H. odorata* and possibly also sometimes *S. parvifolia*, *S. ovalis*, *S. argentifolia* and *S. macrophylla* can also exhibit true polyembryony.

The dipterocarp fruit is trilobular and each loculus as a rule has two ovules. Foxworthy¹² noted long ago that several seedlings habitually germinate from fruit of *S. resinosa* Foxw., and we have observed as many as 18; from our counts (several seedlings from one tree) this species is triploid ($2n = 3x = 21$). Other dipterocarps in which multiple seedlings have been recorded include *Dipterocarpus alatus* Roxb., *D. tuberculatus* Roxb. and *Shorea robusta* Gaertn. f., all of which are gregarious species of the Asian seasonal tropics¹², and the semigregarious African savanna dipterocarps *Monotes kerstingii* Gilg, *M. ? elegans* Gilg and *M. madagascarensis* Humb. (subfamily Monotoideae)¹³. Among 16 Malayan dipterocarp species studied quantitatively by us at least 10 sometimes produce multiple seedlings. It is yet to be confirmed whether in these apomixis is associated with production of multiple seedlings other than in the cases mentioned here; we assume from studies to be published elsewhere that at least in *S. resinosa* and *S. macrophylla*, and it is possible, of course, that adventive embryony occurs in seeds of these and other species in which single embryos develop as well. The percentage of seeds yielding multiple seedlings was estimated in several individuals of *S. agami*, *S. ovalis*, *S. parvifolia* and *S. macro-*

Table 1 Reproductive characteristics of some Malayan Dipterocarpaceae as evidence for apomixis

Species	Chromosome no.	Putative self-compatibility	Pollen germinability	% Seed with multiple seedlings*	Embryological evidence for apomixis	Understorey (U), main canopy (C) or emergent (E)

ptera; in each species some trees yielded a high proportion and others few or none.

Maguire¹⁴ has inferred apomixis in *Clusia* (Clusiaceae) from Guyana. One of us (C.O.H.) has obtained successful fruit set on bagged female inflorescences of the wild dioecious understorey fruit tree *Garcinia parvifolia* Miq. of Western Malesia, in the same family. It is not yet confirmed whether embryos develop from the inner integument as in the cultivated mangosteen (*G. mangostana*)⁷. This species has a high, probably polyploid chromosome number ($2n = 60$).

Though it can hardly be claimed that this preliminary evidence adequately represents a tree flora which in the lowlands of Peninsular Malaysia alone runs into thousands, it does conclusively demonstrate the occurrence of apomixis in both emergent and understorey trees of the mature phase. Further, if the close relationship between the small genus *Lansium* and the large *Aglaia* is accepted, all the cases demonstrated are from the series of closely allied species which occur together in the same habitat and which distinguish Malaysian from other tropical forests. Although it is premature to consider these series as themselves evidence of apomictic reproduction comparable to *Hieraceum* or *Rubus*, it is no longer possible to discount the contribution of apomixis to the evolution of some of them and to the high floristic diversity characteristic of lowland tropical rain forest. Western Malesia seems to have had a more uniform climate during the Pleistocene¹⁵ than other continental regions of the humid tropics. If we assume that natural selection in these forests is dominated by biotic factors¹⁶ and that immigration and extinction are continuing, we must conclude that the selective factors are constantly changing, and that few apomictic biotypes will survive for prolonged periods. This suggests that series of allied taxa which include apomicts are evidence for continuing active diversification.

We thank Professor Forbes W. Robertson and J. Muller for helpful suggestions, and Professor A. N. Rao and N. Prakash for guidance in embryology. We thank the Leverhulme Trust Fund, the Royal Society, NERC and the Carnegie Trust for support.

Regularity versus irregularity in specific songs of closely-related drosophilid flies

THE songs of most insect species are stereotyped and show regular rhythms^{1,2} which can be readily defined and described. In such cases, closely related species produce songs which differ in rhythmic structure³⁻⁵, carrier frequency^{5,6} or combinations of these parameters^{3,7}. We have examined the songs produced during courtship of the sibling drosophilid fly species *Zaprionus tuberculatus*, *Z. sepioides* and *Z. mascariensis* which are known from morphometric⁸ and chromosomal evidence to be closely related. Drosophilid songs are produced by wing beating and normally consist of a regular series of similar mono- or polycyclic sound pulses with carrier frequencies of 150 to 500 Hz and pulse periods of 8 to 250 ms (for review, see ref. 9). Some species produce more than one type of song, and the pulsed song may be interrupted by protracted bursts of constant frequency tone¹⁰.

Flies were lightly etherised on the day of emergence and the two sexes were isolated in groups of 10 to 30 into vials containing fresh standard food: 10-15 d later, one individual of each sex was placed in a 12 × 12 × 20 mm wire gauze cage within 5 mm of the ribbon of a Grampian GR4 microphone (for further information on the acoustics and methods see refs 9, 10). During courtship, flies were watched through a binocular microscope and sounds were monitored through headphones as they were produced. Sound records were made at between 18 and 20 °C using amplifiers onto a Tandberg 3341X tape recorder and subsequently oscillograms were made using a Nihon Kohden PC 2 B moving film camera.

Records were analysed by direct measurement from the oscillograms of pulse period. In addition, the number of pulses making a discrete sequence, separated by at least 1 s from adjacent sequences or by a change of character of 5 pulses duration were measured. Individual sequences were analysed as follows: the mean period and its standard deviation were calculated. From these, variance ratios were obtained and Student's *t* test was applied between the pulse periods in song sequences produced by different individuals of a species and between pulse periods in the songs of two species. In addition, the Kolmogorov-Smirnov test for exponentiality (*D* test)¹¹ was applied to pulse periods in individual sequences of the song of all three species.

Subjectively, the songs of both *Z. tuberculatus* and *Z. sepioides* sounded very regular, with long uninterrupted sequences of regular sound pulses. Analysis showed that each species produced two songs, a short period song which was similar in both species and a long period song of significantly longer period in *Z. sepioides* than in *Z. tuberculatus* (Table 1). In both species, the variability in pulse period within a sequence of song of either type was similar. The type 1 song of *Z. tuberculatus* is produced in longer sequences than that of *Z. sepioides*, but sequence duration is highly variable in both species.

By contrast with the songs of the other two species, that of *Z. mascariensis* always sounded erratic. The duration of a sequence was hard to define and the pulse period within a sequence was highly variable (Table 1). Individual long sequences were tested to find whether the pulse period was random (the *D* test does not discriminate well with short sequences). Of 22 sequences thus analysed, produced by seven individuals, 12 did not differ significantly from randomly produced sequences. All of the other 10 sequences, while showing some pulses produced with a fairly regular short period, also contained

Table 1 Comparison of parameters of songs produced by three species of male *Zaprionus* (Drosophilidae) during courtship at 18–20 °C

Species	Mean pulse period $\pm\sigma$ (ms)	Type 1 song No. of sequences measured	Mean sequence duration $\pm\sigma$ (ms)	Mean no. of pulses per sequence	Mean pulse period $\pm\sigma$ (ms)	No. of sequences measured	Type 2 song Mean sequence dura- tion $\pm\sigma$ (ms)	Mean no. of pulses per sequence $\pm\sigma$
<i>Zaprionus tuberculatus</i> (7)	12.37 \pm 1.32 <i>n</i> = 183	7	730 \pm 531 <i>n</i> = 10	68.3 \pm 50.9 <i>n</i> = 10	26.64 \pm 3.48 <i>n</i> = 240	12	897 \pm 694 <i>n</i> = 10	28.7 \pm 20.7 <i>n</i> = 10
<i>Zaprionus sepsoides</i> (8)	11.23 \pm 1.90 <i>n</i> = 356	14	325 \pm 173 <i>n</i> = 15	29.2 \pm 15.83 <i>n</i> = 15	41.95 \pm 5.21 <i>n</i> = 284	13	1372 \pm 630 <i>n</i> = 15	31.9 \pm 12.96 <i>n</i> = 15
<i>Zaprionus mascariensis</i> (7)	—	—	—	—	81.69 \pm 101.14 <i>n</i> = 880	36	2267 \pm 2162 <i>n</i> = 36	24.9 \pm 21.4 <i>n</i> = 36

Even though the song of *Z. mascariensis* differs from both song types in the other two species, it is treated for the purposes of comparison here as if it were type 2 song. Numbers in parentheses after specific names indicate the individual flies recorded.

long series of erratic pulse periods which were never found in the songs of the other two species. These nonrandom song sequences had a shorter average pulse period and less variability of pulse period than the random sequences (Table 2) but were very significantly more variable than either type of song of the other two species. Although it appears from Table 1 that the duration of song sequences is longer and more variable in *Z. mascariensis* than in the other two species, this is complicated by the fact that in the other species, complex sequences of type 1, then type 2, then type 1, 2–1–2 and several longer combinations have been observed.

It has been shown that the songs of various closely related

which will accept ever more random signals and mechanisms of motor patterning which override the normally rhythmic flight¹⁹ and song-producing mechanisms²⁰.

Irregularity versus regularity as a specific character of insect song has apparently not been previously observed and is thus a rare phenomenon. The situation may be explained as follows: if regularity has evolved, the production and recognition templates will tend to co-evolve and to tighten the song regularity; this is commonly observed. If irregularity once evolves through relaxing of the selective pressure it will tend to proceed to the point of randomness when challenged by nonrandomness; this is what we describe here. Once randomness has evolved, how-

Table 2 Characteristics of song sequence of male *Zaprionus mascariensis*

	No. of sequences observed	Mean pulse period and s.d. (ms)	Mean sequence duration and s.d. (ms)	Mean no. of pulses per sequence and s.d.
Random sequences	12	104.8 \pm 107.2 <i>n</i> = 390	4082 \pm 2685 <i>n</i> = 12	33.6 \pm 22.2 <i>n</i> = 12
Nonrandom sequences	10	53.3 \pm 77.8 <i>n</i> = 405	2319 \pm 1210 <i>n</i> = 10	40.7 \pm 15.2 <i>n</i> = 10
Short sequences	14	111.4 \pm 132.4 <i>n</i> = 85	675 \pm 532 <i>n</i> = 14	6.07 \pm 3.12 <i>n</i> = 14

Short sequences have been taken as those composed of 2–12 pulses which cannot readily be tested for randomness. Nonrandom sequences have a probability of less than 0.05 using the Kolmogorov–Smirnov *D* test¹².

Drosophila species differ in pulse period^{11,13}, and that this difference is an important parameter in courtship success of the male fly and in species isolation^{14,15}. Doubtless such differences are important in distinguishing the rhythmic songs of *Z. tuberculatus* from those of *Z. sepsoides* but it seems that the best character of the song of *Z. mascariensis* by which it can be distinguished from that of the other species is its greater variability and irregular structure. Several advantages have been suggested for the variable song repertoire of birds: that they may be important for individual recognition, in sexual selection or in territorial behaviour (for review see ref. 16). Bird songs, however, do not sound like random sequences, nor are the individual phrases usually as simple as the song pulses of drosophilid flies. Irregularity of the type found in the song of *Z. mascariensis* implies that the female fly has a recognition mechanism capable of accepting irregular sequences and of rejecting regular sequences.

The normal insect situation seems to be that the recognition–production template (for a review of this concept, see ref. 17) is selected to accept ever more stereotyped songs which differ greatly from those of related species from which sexual isolation is desirable¹⁸; this is seen in the type 2 songs *Z. tuberculatus* and *Z. sepsoides* which differ at a level of probability of more than 10^{–6}. By contrast the songs of *Z. mascariensis* which seem to be selected for variability versus regularity will require templates

ever, it is in itself a stable situation from which it is hard to evolve and which therefore is likely to become extinct rapidly and to be rare.

This work was carried out at the Laboratoire de Biologie et Génétique Evolutives, CNRS, 91190 Gif-sur-Yvette, France, as part of a larger and continuing project on the evolutionary biology of drosophilid flies. We pay tribute to the late C. Bocquet, Director of the Laboratory, and thank Drs R. Dawkins, F. H. C. Marriott and J. R. Krebs for advice and assistance, Mme M.-T. Chassagnard for technical assistance and Dr L. Tsacas for initiating the project and for continual support, advice and encouragement. The project was supported by research grant ATP Internationale no. 2164 and RCP no. 318 of CNRS awarded to Dr L. Tsacas.

Semicircular canals in squids

THE cephalopods and fishes are rivals as fast-moving predators and they show many parallel adaptations¹. We present here evidence that in squids and cuttlefishes the statocysts possess semicircular canals, though of rather imperfect form. Animals that move quickly need to monitor angular rotation in order to allow appropriate adjustments of the eyes as they turn. To provide this facility certain critical physical requirements must be met and semicircular canals provide this. Their small size ensures that during rotation the pattern of flow is dominated by viscous damping. Consequently the actual volume of fluid flow is small, permitting "accurate transduction of the volume displacement of fluid by means of a water-tight 'swingdoor' cupula having limited angular excursion in the ampulla"². Furthermore, in vertebrates, the low Reynolds number of the system (less than one) ensures that "the velocity of relative flow becomes strictly proportional to the inertial force driving it and hence to the angular acceleration of the head". The statocysts of the fast-moving cephalopods have gone some way to meet these requirements by their shapes, and by the arrangement of the strange anticristae, projections that partly divide the cavity.

The crista of the statocyst is orientated in several planes³ and is sensitive to both angular and linear acceleration⁴. Further investigation now shows that in squids and cuttlefishes the cavity is shaped to direct the flow of endolymph along specific channels, across which the cupulae of the cristae are placed (Fig. 1). We have studied the canals after fixation and staining

Fig. 1 Horizontal canal of *Loligo vulgaris* of 14 cm mantle length. Left side, seen from behind. The cupula is stained with diluted squid's ink. In all the figures the anticristae and hamuli have been given the numbers used by Dilly, Stephens and Young⁵. CTA and CTP are the anterior and posterior transverse cristae; CL, longitudinal crista; CV, vertical crista; cup., cupula; n.cr., crista nerve; Köf., Kölliker's canal; s., statolith; h1-5 are the hamuli, and the straight anticristae are numbered 1-7.

Fig. 2 Left statocyst of *L. vulgaris* stained with haemalum. Seen from above it shows the cupulae on the cristae.

the inside of the statocysts by injection of haemalum or of ink, and by reconstructions from serial sections.

The canals are not complete tubes but are grooves, made by bulges in the outer walls of the sac. The canals are partly enclosed by the projections of cartilage that have been called anticristae³. These projections are of two sorts⁵ (Figs 1 and 2). Some are placed at the turns of the crista, where they bend over as hooks, and these have been called hamuli and numbered h1-h5. Elsewhere the anticristae are straight projections (numbered 1-7) with various shapes, arranged in rows so as to divide the cavity into channels. In an adult *Loligo* some of the anticristae become joined together to make complete tunnels, restricting the flow of endolymph (Fig. 3). Some of the anticristae become shaped and grooved along the lines of flow (Fig. 3).

The most fully developed canal, with a nearly complete tunnel, is the horizontal one, related to the vertical section of the crista and thus monitoring angular accelerations to right or left (yawing). These turns about the vertical axis, produced by the animal's own steering, obviously require corresponding adjustments, especially of the eyes. Movements in the rolling plane, monitored by the longitudinal crista, are smaller and not initiated by the animal itself. The corresponding canal does not have any part that forms a complete tunnel. However, this canal is more complete in *Sepia* than in *Loligo* because in the former there is a large hamulus at the first turn of the crista which is absent in *Loligo*. The anterior transverse crista, along the front of the cavity, monitors movements in the pitching plane and is activated by the endolymph in a deep channel above and below it, but again without a covered tunnel.

The function of the posterior transverse crista is more difficult to decide. It may be activated by movement in the pitching plane, as indicated by the arbitrary lines shown in Fig. 4. Possibly the two transverse cristae serve separately to monitor movement in the two directions, head up and head down, a function that is performed in the other planes by the paired statocysts. However, we suggest that it may (also?) serve to monitor linear accelerations, both forwards and backwards⁶. Squids and cuttlefishes have special need for receptors to monitor these movements produced by their jets. No fish has equal powers of movement in both directions. The channel behind this crista extends far backwards and the slope in front of it is gently downwards. This hypothesis is supported by the fact that the crista faces upwards (Fig. 4) so that its cupula

stands more nearly vertically than those of the anterior transverse and longitudinal cristae, which are horizontal (Fig. 2).

The details of the statocysts vary with the habits of the animals. The anticristae are all more smoothly rounded in *Sepia* than in *Loligo*. *Sepioteuthis* is a squid which resembles *Sepia* in shape, but, of course, is without a cuttlebone. Its anticristae are also rounded, like those of a cuttlefish; perhaps this form is a result of smooth rotatory movements with the fins.

The anticrista at the front of the statocyst (number 1) is rounded and single in *Sepia* but pointed and double in *Loligo* (Fig. 4, numbers 1 and 1a). In the small, inshore, bottom-living squid *Alloteuthis* this anticrista varies greatly between individuals, sometimes forming a plate, sometimes a whole crowd of little knobs. This region lies in the path of movement of endolymph in several planes (Fig. 4) and anticrista 1 is evidently different from all the others. In *Loligo* it is covered with sensory hairs⁵, and perhaps these are receptors serving to monitor acceleration in several planes. *Alloteuthis* has a long rigid spike or 'tail' and this animal may make movements that impose special requirements on the statocyst and produce the varied knobs at the position of anticrista 1.

In cephalopods that turn slowly, such as octopods, or decapods that live in deep waters, the anticristae are reduced^{7,8}. No doubt this is because sensitivity to slow movements requires a large inertial mass of fluid. Conversely, detection of rapid changes in acceleration would be impaired by a large mass, and the rapidly moving decapods avoid this by developing the anticristae and forming partial tubes.

It is interesting to compare the dimensions of the canals of decapods with those of fishes. The radius of curvature (R) of the horizontal canals of four large *Loligo forbesi* gave a mean value of $R = 1.25$ mm. These animals were all around 37 cm in length and weighed about 1 kg (in air). In fishes of this weight the radius was about 5 mm (ref. 9). The internal radius (r) of the channel in the squids, at its narrowest point, was about 0.4 mm, whereas in the fishes it was 0.2 mm. Interpretation using weight for comparison is obviously difficult because of differences in buoyancy. In the cephalopods the small value of R may compensate for the fact that the canals are incomplete and r is

Fig. 3 Thick section of the right statocyst of a large *Loligo forbesi* (48.5 cm mantle length). Seen from the lateral side, to show the fusion of anticristae 2 and 3 and 6 and 7 to make a nearly complete horizontal canal. Anticrista 7 has become elongated along the line of flow. The cupula is very lightly stained and has been touched up. Stained with haemalum.

Fig. 4 Right statocyst of a large *L. forbesi* (37 cm mantle length). Seen from above. The presumed directions of flow are shown by arrows. Stained with haemalum. The photograph has been retouched to show the crista more clearly.

large. However, nothing is known of the elastic and other properties of the cupulae, and it is not known whether they allow any flow of fluid past them. Like Budelmann we have seen some appearances suggesting that there may be attachments of the cupulae to the hamuli, perhaps serving to make the channels more nearly 'water-tight'.

It is clear that these devices for canalising flow in the statocyst have the same function as the semicircular canals of vertebrates and the somewhat similar arrangements in Crustacea¹⁰. We must, therefore, add one more to the long list of parallels between the functional organisation of cephalopods and vertebrates¹.

The material for this work was collected at the Marine Biological Laboratory, Plymouth and the Zoological Station, Naples and we thank the Directors and staff of these laboratories for their help. We also thank Dr M. Nixon for help in preparing this paper, Mr C. Carter for photographs, the Wellcome Foundation for support and the Wellcome Institute for the History of Medicine and the Department of Zoology, University College for accommodation and assistance.

Development of eye alignment in cats

WHEN the eyelids of newborn kittens open, casual observation of the pupils suggests that the eyes must be divergently misaligned. Pupillary divergence may be quantified by photographing the eyes while the cat is facing a distant light source. The images of this light, formed by reflection at the corneas, coincide approximately with the optical centres of the eyes, and the distance by which the separation of the pupils exceeds the separation of these images is defined as pupillary divergence¹⁻⁵. It declines with increasing age until some time during the second month². Although it is reasonable to assume that the visual axes are also divergent before this age, this assumption leads to a paradox because surgical misalignment of the eyes of young kittens is known to disrupt binocular connections in striate cortex⁶. Moreover, development of normal orientation selectivity in kitten cortex may require early coordinated binocular vision⁷. We have examined this problem using a combination of techniques with which we are able to determine the alignment of the visual axes in the alert cat. Our results show that while the pupillary axes are quite divergent during the first few weeks after birth, the visual axes are not divergent. It is thus possible that kittens experience synchronised binocular vision very early in life.

The four steps required in the method we use are illustrated in Fig. 1. First, the cat is photographed while alert, as shown in (a). An aperture, positioned in front of a tungsten light source 2.4 metres from the cat, produces a small, well-defined corneal image in each eye. Second, within one day, the cat is prepared for electrophysiological study of single neurones in the visual cortex. The paralysed cat is placed in a stereotaxic

Fig. 1 The steps required to obtain visual axis alignment in the conscious cat. In humans the visual axis or line of sight is defined by a line from the fovea of the retina to the object of fixation passing through the nodal plane of the eye (the nodal plane defines equal magnification between object and image space). In cats we define the visual axis as a line from the centre of the area centralis through the nodal plane to the object of regard. In (a) an alert cat faces a camera and a light source (bottom). The distance by which each pupil centre (+) diverges from the orneal image of the light source (●) is shown (top). The cat is prepared for physiological study and photographs are again taken as shown in (b). To obtain the factor for converting linear to angular divergence, photographs are taken with the camera and light source rotated 10° along an arc (c). Finally, the animal prepared for single-cell study of striate cortex. The angle between the visual axes is then determined by plotting binocular receptive fields as shown in (d).

assembly so that its position is nearly the same as when it was alert and several photographs are again taken, as shown in (b). Third, in order to find the factor for converting linear divergence of the pupils into angular divergence of the pupillary axes, the camera and the light source are shifted 10° along an arc from the previous position, as depicted in (c), and another series of photographs is taken. The fourth step (d) is to plot the receptive fields for several binocular cells recorded from the striate cortex. The mean distance between the centres of these receptive fields is used to determine the angle between the visual axes.

Animals are prepared for physiological study by standard techniques. Anaesthesia is induced with Fluothane, a vein is cannulated, and anaesthesia is maintained with Brevital (sodium methohexital). A tracheal tube is inserted, scalp bone and dura mater are removed, and tungsten-in-glass electrodes are inserted at the crown of the post-lateral gyrus to penetrate in Area 17 within the representation of the area centralis. The animal is paralysed and maintained with a Flaxedil (gallamine triethiodide)-glucose solution. Peak expired CO₂, electrocardiogram and electroencephalogram data are monitored continuously. Spikes from single neurones are amplified and displayed by standard means. Optimal stimuli are determined for each cell and receptive fields are plotted for individual binocular neurones in the visual cortex.

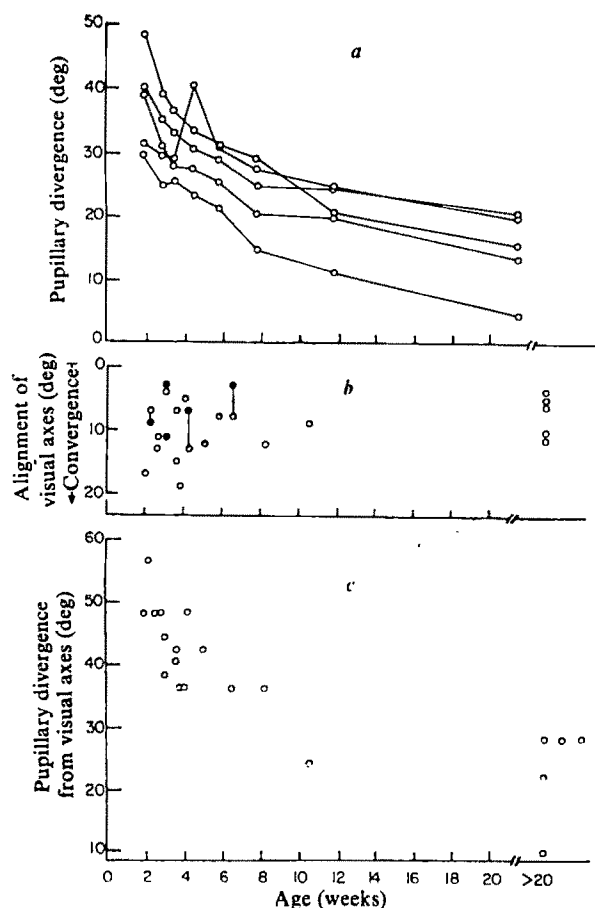

Negatives are processed, mounted in slide holders, and magnified by projection to enable accurate measurements of pupillary divergence. An exact magnification factor is obtained for each photograph by use of a ruler positioned just above the cat's head in the plane of its corneas.

Using the procedure described in step 1, we have measured the angle between the pupillary axes at successive stages of development for a number of kittens. Figure 2a shows these data for five animals. As found previously², there is marked divergence in the youngest kittens which decreases, but does not entirely disappear, with increasing age.

In order to measure visual axis alignment during this period, we have used the four-step procedure described above. Each of 21 animals was studied once at a particular age. By plotting receptive fields (step 4 above), we are able to measure the angle between the visual axes in the paralysed animal, and since we know how interocular alignment has changed between alert and paralysed states (steps 1-3 above), we are able to infer visual axis alignment in the awake cat. Results of this determination are shown in Fig. 2b. Each open circle represents the angle between the visual axes of an alert cat of a given age. The result is markedly different from that which might be anticipated on the basis of measurements of pupillary divergence. From the earliest age, 2 weeks, all cats are convergent rather than divergent. The magnitudes of convergence are somewhat surprising. This may indicate that alert cats converge excessively under our experimental conditions or that a small systematic error is introduced by our method. In either case, two conclusions may be firmly drawn. First, no trend is evident which suggests that visual axis alignment changes with age. Second, for some positions in object space, cats seem able to receive corresponding binocular input at all ages tested.

If visual axis alignment is relatively constant with age but the angle between the pupillary axes changes substantially, then the angle between the visual and pupillary axes must also vary. This angle is given for cats of different ages in Fig. 2c. Each point represents the angle of pupillary axis divergence if visual axes are assumed to be parallel. These data show a close match between the magnitude and time course of the anatomical changes and the differences in pupillary divergence indicated in Fig. 2a.

Before drawing conclusions from these findings, we must consider a few potential difficulties in our methods and the controls devised to deal with them. First, use of the pupil as a reference for mensuration depends on the assumption that its position remains constant throughout our procedures. Constriction may not be symmetrical however, and pupil centres may shift when the necessary local and systemic paralyzing and

ophthalmic drugs are used. Even small changes could cause considerable errors in determining interocular alignment. To provide an alternate fiducial point to the pupil, very small tattoos made with titanium oxide in saline were placed on the corneas of several cats. Measurements of visual axis alignment based on the use of these tattoos are included in Fig. 2b (filled symbols). When both the tattoo and pupil techniques are used for the same cat, the two points are connected by a vertical line (open to filled symbols). It is clear that the data obtained using tattoos are in agreement with those of the other method. Thus, it seems that no systematic errors result from the use of pupils.

Another possible source of error is concerned with the influence of luminance level. To obtain accurate measurements using pupils, it is necessary to cause constriction by use of high luminance or drugs or both. It is possible that the light levels we use may influence our results. In particular, reflex convergence might occur, and this possibility must be thoroughly explored, as we find that cats are somewhat convergent at all ages. Using tattoos, we were able to take photographs with room illumination only as well as under higher luminance levels (from 50 to 3,000 cd m^{-2}), and we determined that no significant light-induced convergence occurred.

Apart from these considerations, our procedures involve other potential sources of error. Cyclotorsional changes could confound measurements of strictly lateral displacements. Eye drift could occur between the time that photographs of the immobilised animal are taken and the time receptive fields are plotted. Contact lenses, which are inserted before receptive field study, could cause displacement of the eye or prismatic changes of the visual axis. We have ruled out each of these possibilities. Cyclotorsional alignment has been measured under all conditions, and our findings are reported elsewhere⁸. Possible effects due to eye drift and contact lens use have been determined

Fig. 2 a, The pupillary axis is defined by a line perpendicular to the cornea that passes through the centre of the eye's entrance pupil (the entrance pupil is the image of the real pupil formed by the cornea). The angle of divergence between the pupillary axes may be obtained from the amount of pupillary divergence measured using photographs. By taking photographs at several angles relative to the cat, we have determined that linear and angular divergences are related by a constant factor (mean for all cats: 15.4 deg mm^{-1}). With the conversion factor and photographs taken before and after immobilisation, it is possible to deduce the angular change in pupillary alignment, and thus in visual axis alignment. Angular divergence of the pupillary axes of the alert kitten decreases with increasing age, as shown for five kittens photographed at regular intervals during development. The distance in mm by which separation of pupil centres exceeds separation of corneal reflexes is converted into degrees through use of the empirically determined conversion factor mentioned above. Each point represents a mean value based on eight photographs. **b,** The angle between the visual axes is operationally determined as follows. The electrode is placed within the Area 17 representation of area centralis. The receptive fields of cells in this region, because they represent homologous retinal points, are separated by the same distance on the plotting screen as those from the centre of the area centralis. Thus the angle between the visual axes is the inverse tangent of the distance between receptive field centres minus inter-pupillary distance divided by the distance between the cat's eyes and the stimulus screen. Visual axis alignment is convergent in cats of all ages. \circ , Represent values based on the four-step procedure illustrated in Fig. 1. \bullet , Depict values obtained by a method in which corneal tattoos were used similarly to the pupils as eye alignment reference points. In cases where pupils and tattoos were used for one animal, \bullet and \circ are joined by a vertical line. **c,** Angular divergence of pupillary axes relative to visual axes (that is pupillary divergence if the visual axes were parallel) decreases with increasing age. Each point is obtained from a single paralysed animal through combined use of receptive field and photographic measurements. Magnitude and time course of the anatomical change illustrated here match those of the change in pupillary divergence shown in (a) above. Data points in (b) and (c) were obtained from the same animals.

to be negligible by photographing several times during paralysis for some cats, monitoring eye positions through ophthalmoscopic projection of the optic discs, and by plotting receptive fields with and without contact lenses in place. Sources of variability inherent in our measurements include those related to photographic processing and the plotting of receptive fields. We have analysed each of these factors and find that the overall variability in our procedures is exceedingly small.

We conclude that the visual axes are not divergent in young, alert kittens. This finding is contrary to what may be inferred from pupillary photography alone, and also from receptive field separation in very young paralysed animals⁹. Because the visual axes of young kittens are convergent, it seems likely that fused binocular vision of objects at some distances occurs during early life. Further work is required to confirm this speculation.

Fatty acids, aldehydes and alcohols as attractants for zoospores of *Phytophthora palmivora*

ZOOSPORES of the important plant pathogenic fungi *Pythium* and *Phytophthora* are attracted to plant roots and to exudates and extracts from roots¹. Attraction (positive chemotaxis) to amino acids^{2,3} which occur in root exudates, and ethanol⁴, which will be produced by roots in waterlogged soils, has been demonstrated, but no substance has been found which by itself is as powerful an attractant as root exudate. The attractiveness of root exudates must therefore be explained by additive or synergistic effects between the known attractants, or by powerful attractants which have hitherto escaped detection, or both. There is evidence for additive and synergistic effects⁵, but the fractionation of root exudates has not so far yielded evidence of additional chemotactic factors. We report here the existence of further attractants for fungal zoospores, and consider the possibility that they may be of significance in chemotaxis to plant roots.

Our experiments were carried out with *Phytophthora palmivora* (Butler) Butler, which attacks a range of tropical crops, especially cocoa (*Theobroma cacao* L.), in which it infects pods, roots and other parts⁶. Chemotaxis of zoospores to cocoa root exudates has been demonstrated⁷, as well as to pod extract⁸ and some amino acids^{2,9}. We used, under licence from the Ministry of Agriculture, Fisheries and Food, the same strain that we used in a study on negative geotaxis of zoospores⁸, and a swim-in test in which the number of zoospores entering a capillary tube containing a suspected attractant are counted and compared with numbers entering a control tube¹. Attraction of *Ph. palmivora* zoospores to some amino acids^{2,9} was confirmed, and in addition they were shown to respond, as do *Phytophthora cinnamomi* zoospores¹, to ethanol. Other alcohols, aldehydes and fatty acids were investigated. Allen and Newhook¹ had mentioned that *Ph. cinnamomi* showed chemotaxis to 5 mM solutions of methanol, *n*-propanol, *n*-butanol and acetaldehyde, but of these compounds we find only acetyldehyde active with *Ph. palmivora*. Several alcohols, aldehydes and fatty acids, however, were shown to be attractants, some of them having thresholds considerably lower than those for ethanol or any other attractant so far established for fungal zoospores (Table 1). The most potent attractants had 4–6 carbon atoms, iso- compounds tended to be more effective than those with straight chains, and acids and especially aldehydes were usually more powerful than the corresponding alcohols. After entering the capillary tube, zoospores soon settled, encysted and germinated, although some compounds at high concentrations caused lysis instead of encystment. Isovaleraldehyde, for example, resulted in lysis at 10 mM, some lysis but some encystment and germination at 1 mM, and complete germination in the range 0.001–0.1 mM. We have also found that zoospores of *Ph. palmivora* are repelled by H⁺ and other monovalent ions, as are those of *Ph. cinnamomi*¹². Taking into account these repellent effects, experiments on adjusting the pH of attractants have been carried out. These experiments indicate that the fatty acids are attractive in the unionised (R.COOH) but not the ionised state (R.COO⁻). Hence, the new attractants have the common feature of volatility.

Are these new attractants likely to be of significance in nature? In order to ascertain whether such compounds are important in chemotaxis to plant roots, it would be necessary to fractionate root exudates before chemotactic tests in a way that avoids the loss of volatile components. The procedures so far used are unlikely to avoid such losses and hence volatile attractants might have been overlooked.

Zoospore suspensions ($1-2 \times 10^5$ spores ml⁻¹) were prepared as previously reported⁸ except that the suspending medium into which spores were released was 0.5 mM potassium phosphate buffer (pH 5.8) + CaCl₂ (0.05 mM) + MgCl₂ (0.05 mM). Capillary tubes (1 µl) were filled with the substance under test dissolved in suspending medium and adjusted if necessary to pH 5.8 with 1 M NaOH, or the suspending medium alone (control) by heat sealing one end of the capillary and allowing the liquid to be drawn into the tube as it cooled¹⁰. A test and a control capillary were placed at opposite ends of an assay chamber (20 × 6 × 1 mm deep) which was then filled with a zoospore suspension and covered with a coverslip. After 10 min, spores were immobilised by gently warming the chamber, and the spores inside the two capillaries were counted. Five replicates were carried out with each concentration of a substance tested and the probability of any higher count obtained with the test capillary as compared with the control capillary being due to chance was determined by means of the *t* test for paired samples¹¹.

*Except where indicated as iso- or tertiary, the straight-chain (*n*) compounds were used.

†Attraction by concentration 10 mM, with $P < 0.01$; 0 = no attraction; ? = apparent attraction towards, but not into, capillary.

‡The lowest concentration of an already proved attractant giving attraction with $P < 0.05$.

Fries¹³ states that with gas chromatography pea roots give 'a rich spectrum indicating the presence of numerous volatile compounds' and cites references establishing the production of volatile alcohols, aldehydes and organic acids (including valeric acid) by plant roots, fruits and other parts. Hence the compounds shown in the present study to be chemotactic may well be present in fresh root exudates and have a role in attraction. This may be true of related compounds, such as unsaturated fatty acids, which are known to be produced by roots¹³ but which we have not tested.

We thank the SRC for a studentship to J.N.C.

Cell division factors (cytokinins) from irradiated plant tissue

REPORTS on the effects of ionising radiation on plant cells in callus culture are quite limited. Work on a few species¹⁻³ has shown that low doses of γ radiation, starting at 0.5 krad, stimulate callus growth and differentiation. Larger doses ranging from a few krad to about 20 krad inhibit growth and differentiation, respectively. High doses (16 krad and above) have been shown to alter culture media components chemically and thereby affect cell growth⁴ and differentiation⁵. We now report that

Fig. 1 Tobacco callus cytokinin bioassay of paper chromatographic R_f zones from extracts (140 g equiv. fresh weight) of irradiated (1-2 krad) (a) and nonirradiated (b) *Haworthia* tissue. Tissue (0.4 kg) was blended in a Waring blender with sufficient cold absolute ethanol to obtain a final ethanol concentration of 70% assuming all the tissue to be water. The mixture was shaken in the cold for 8 h and filtered through gauze. The solid residue was resuspended in additional cold 70% ethanol, shaken for 4 h and filtered. Filtrates were combined, adjusted to pH 2.5 with HCl and passed through a Dowex 50W-X8 cation exchange column (2.9 \times 15 cm, 50-100 mesh, H⁺ form). The column was washed with 150 ml of distilled water and cytokinins were eluted with 150 ml of 2M NH_4OH followed by 350 ml of 6M NH_4OH . Ammonia was removed from the eluate under an air stream and the remaining aqueous solution was taken to dryness in a vacuum. The dry residue was extracted with 95% ethanol and the ethanolic solution was reduced to a small volume and strip loaded on Whatman 3MM paper. Ascending chromatography was carried out overnight using 2-butanol: concentrated (28% NH_3) NH_4OH (4:1, v/v) and chromatograms were dried, cut transversely into 10 equal R_f strips and eluted with 95% ethanol. Aliquots from each strip were bioassayed for cytokinin activity. Samples for bioassay were dried in a vacuum in 50-ml flasks; 25 ml of nutrient agar medium^{8,9} was added to each, and the flasks were autoclaved (20 min at 18 pounds per inch²). Three pieces of Wisconsin 38 tobacco pith callus (approximately 150 mg per piece) were placed in each flask and the cultures were maintained in diffuse light at $23^\circ \pm 2^\circ \text{C}$. After 5 weeks, tissues were collected and fresh weights were recorded. The broken lines show callus yield on basal bioassay medium; kinetin at $5 \mu\text{g l}^{-1}$ yielded 3.01 g of tobacco callus.

Fig. 2 Tobacco callus cytokinin bioassay of Sephadex LH-20 column fractions (25 g equiv. fresh weight) after chromatography of paper R_f zones 0.4-0.8 (Fig. 1) from irradiated (a) and nonirradiated (b) *Haworthia* tissue. Eluates of paper R_f zones 0.4-0.8 from irradiated tissue were taken to dryness and the residue was dissolved in 1 ml of 35% ethanol and loaded onto a Sephadex LH-20 column (2.5 \times 90 cm). The column was eluted with 35% ethanol and forty-eight 30-ml fractions were collected and bioassayed for cytokinin activity according to the procedure described in Fig. 1. Authentic samples of zeatin and zeatin riboside were chromatographed in the same conditions and their elution positions are indicated by Z and ZR, respectively. The broken lines show callus yield on basal bioassay medium; $5 \mu\text{g l}^{-1}$ kinetin yielded 3.42 g of tobacco callus.

gamma irradiation (1-2 krad) of *Haworthia* in callus culture results in the formation of cytokinins⁶—cell division factors—not detected in nonirradiated tissue.

Tissue was excised from surface sterilised inflorescence stem segments of *Haworthia mirabilis* Haw. and cultured on Murashige-Skoog medium⁸ supplemented with synthetic cytokinin (kinetin, 6-furfurylaminopurine, 0.2 mg l^{-1}) and auxin (naphthaleneacetic acid, 0.2 mg l^{-1}). Callus which developed was maintained by subsequent subculture on the same medium containing kinetin and naphthaleneacetic acid (both 1.5 mg l^{-1}). All tissue was kept at $23^\circ \pm 2^\circ \text{C}$ under continuous light.

Callus tissues weighing approximately 350 mg were irradiated using a ^{60}Co γ source. Tissue given 1-2 krad at a dose rate of 0.19 krad min^{-1} grew continuously, became compact and did not differentiate. It could be subcultured repeatedly on hormone (cytokinin and auxin) and *myo*-inositol-free media and showed no diminution of growth. Nonirradiated callus required hormones or *myo*-inositol for continued growth.

Cytokinins were isolated from irradiated tissue 8-10 weeks after third generation subculture on hormone and *myo*-inositol-free medium by a procedure similar to that described for *Populus \times robusta* leaves⁷. Cytokinins were assayed as described in the legend to Fig. 1. Nonirradiated tissue cultured for 8-10 weeks on medium containing kinetin and naphthaleneacetic acid (both 1.5 mg l^{-1}) was analysed for cytokinins in the same way. Figure 1 shows results of cytokinin bioassay of extracts of irradiated and nonirradiated tissue after paper chromatography. There were two zones of activity from irradiated tissue, one at

R_f 0.1–0.2 and a larger response from R_f 0.4 to 0.8. No corresponding response was obtained from nonirradiated tissue. R_f zones 0.4–0.8 from both irradiated and nonirradiated tissue were further purified on a Sephadex LH-20 column using 35% ethanol¹⁰, as described in the legend to Fig. 2.

Five areas of cytokinin activity were obtained from irradiated tissue after chromatography on Sephadex LH-20 (Fig. 2a). The two major peaks centred in fraction 16 and 19 cochromatographed with authentic samples of zeatin riboside (6-(4-hydroxy-3-methyl-2-butenylamino)-9- β -D-ribofuranosylpurine) and zeatin, respectively. Authentic samples of 6-(3-methyl-2-butenylamino) purine and its riboside, both known cytokinins, did not cochromatograph with any peaks of cell division activity from irradiated tissue. Essentially no cytokinin activity was obtained from nonirradiated tissue except a small response in fraction 19 which cochromatographed with zeatin (Fig. 2b). Bulk fractions (200–300 ml each) beyond those shown in Fig. 2 were collected until a total effluent volume of approximately 2,200 ml had passed through the column in the case of the irradiated and of the nonirradiated tissue. Bioassay of these fractions showed no additional cytokinin activity eluting from the column. Chromatography of R_f 0.1 and 0.2 from irradiated tissue on Sephadex LH-20 using the same conditions as described in Fig. 2 yielded a single peak of cytokinin activity centred on fraction 14. This compound eluted before authentic zeatin riboside, our earliest eluting standard cytokinin.

In conclusion, our findings demonstrate that gamma irradiation of plant tissue (*Haworthia*) in callus culture results in the formation of cell division factors or cytokinins. The origin of these compounds and the reason for the diversity of cytokinins in irradiated tissue remain to be clarified. It has been proposed¹¹ that free cytokinins are produced by a pathway that includes synthesis and degradation of cytokinin-containing transfer RNA. The cytokinin content of transfer RNA from irradiated and from nonirradiated tissue is being investigated.

We thank Ms J. Richardson for technical assistance.

Chromosomal rearrangement involved in insecticide resistance of *Myzus persicae*

POPULATIONS of the peach-potato aphid *Myzus persicae* (Sulzer) heterozygous for a particular translocation between autosomes 1 and 3 were first discovered in glasshouses in Great Britain¹. A similar or identical translocation was subsequently found to occur commonly in field populations of *M. persicae* in many parts of the world (Table 1). In tropical and warm temperate regions *M. persicae* is permanently thelytokous², but survival of translocation heterozygotes in the sexual cycle of the aphid,

where a translocation would be expected to impose a severe genetic load³, has also been demonstrated⁴. Considerable resistance to organophosphorus insecticides is common in glasshouse populations of *M. persicae*⁵, and laboratory clones originating from glasshouses and isolated for such resistance are invariably translocated. A link between the translocation and organophosphorus resistance has been suspected, as this could provide the selective advantage which would explain the worldwide occurrence of translocation heterozygotes and their survival in the breeding system. However, no information has been available on the comparative resistance of translocated and normal aphids from most parts of the world. Populations with moderate organophosphorus resistance that appeared in the field on sugar beet in England in 1974 (ref. 6) had the normal karyotype, as also did a resistant clone originating from peaches in France in 1968. Now we report evidence that directly implicates the translocation in the organophosphorus resistance of *M. persicae*.

In Japan, 17 clones of *M. persicae* were tested for their resistance to malathion using a dry film method⁷, with 10 apterae per vial (4×2 cm diameter). Mortalities were recorded 24 h after treatment. The six clones of normal karyotype showed greatest susceptibility to malathion (Table 2). Eight clones with the A1,3 translocation, including a laboratory-reared triploid⁴, showed various degrees of resistance, and one of these had a resistance factor of more than 100. The remaining three clones were heterozygous for an autosome 3 dissociation, which could be the first step in the rearrangement⁴. These also showed different degrees of resistance to malathion.

In England, 100 F₁ clones were obtained from a cross between sexual females (oviparae) from a karyotypically normal, organophosphorus-susceptible clone ('U'), and males from a translocated, very resistant clone (GCRI-1). The latter clone, which was approximately 100 times as resistant to dimethoate as the susceptible parent (U), was derived from a population on chrysanthemums in a glasshouse at Littlehampton, Sussex, and is believed to be a widely distributed clone of *M. persicae* in glasshouses in southern England. Eggs were overwintered in a well-ventilated cage in insectary conditions, and the hatching fundatrices were matured on radish plants and transferred to excised potato leaves in individual cages when adult, to give rise to separate F₁ clones.

URR-0	Field, on <i>Raphanus</i>	A1,3 translocation	60.19	47.02-77.04	103.24

Thirty-five of the 100 F_1 clones were heterozygous for the A1,3 translocation. The other 65 were all of normal karyotype. Deviation from an expected 50:50 ratio⁴ was perhaps due to a hatching delay in aphids carrying the translocation; the clones were set up in approximately chronological order as the fundatrices matured, and only nine of nos 1-50 were translocated, compared with 26 out of nos 51-100.

Starch gel electrophoretograms were prepared from whole-body homogenates of four or five individual adult virginoparae (total weight 1.9-2.1 mg) from each clone, and stained for esterases⁸. All clones were examined in either the third or fourth generation after the fundatrix. There is good genetic⁹ and biochemical¹⁰ evidence that organophosphorus resistance in *M. persicae* is linked with increased carboxylesterase (est-4) activity. All 65 F_1 clones which were karyotyped as normal showed negligible est-4 activity, as in the normal, susceptible parent clone U (Fig. 1). Twenty-eight of the 35 clones which had the A1,3 translocation showed increased est-4 activity, although some samples clearly had less est-4 than the translocated, resistant parent clone, GCRI-1. The remaining seven translocated F_1 clones had est-4 activity characteristic of susceptible aphids. When additional samples of these seven clones were tested, using homogenates of single aphids, it was found that there were some individuals in each clone with increased est-4 activity (Fig. 2). Further studies revealed that est-4 activity varied between individuals in several other translocated F_1 clones, although there were some, like the parent clone GCRI-1, with a stable, high level of est-4.

Thus the translocation and the resistance mechanism show complete linkage, at least when inheritance is through the male. Spermatogenesis may normally be achiasmate in *M. persicae*, as seems to be the case in two species of *Eucera*¹¹. Alternatively, the translocation may maintain its association with resistance by inhibiting crossing over. The question remains as to whether crossover suppression alone is sufficient to explain the frequency of the translocation in natural populations of *M. persicae*. It seems more probable that the translocation results in an advantageous rearrangement of genes contributing to the resistance mechanism. Preliminary studies of inheritance of organophosphorus resistance in *M. persicae* clones without the translocation indicate that at least two alleles are concerned in the regulation of est-4 activity⁹, although it is not known how many loci are involved. The translocation may bring resistance-associated genes which were previously on autosomes 1 and 3 into the same linkage group.

Linkage would be an advantage in itself, but there is some evidence that the chromosomal rearrangement actually enhances resistance by directly affecting gene action or interaction. First, *M. persicae* clones with the greatest organophosphorus resistance and est-4 activity, when examined cytologically, have invariably been translocated. Clone GCRI-1, with greater than 100-fold resistance, is nevertheless only heterozygous for genes conferring high est-4 activity. Second, the resistance of Japanese clones of *M. persicae* with the autosome 3 dissociation could be due to the inactivation of a regulatory locus on this chromosome. Third, the type of intraclonal variation illustrated by Fig. 2 is suggestive of a variegated (V-type) position effect¹²,

Fig. 1 Electrophoretogram showing linkage between a chromosomal translocation and increased est-4 activity in *M. persicae*. Parent clones GCRI-1 and U are on the extreme left and right of the gel respectively. In between are 16 representative F_1 clones, the eight to the left being translocated and the eight to the right being of normal karyotype. Each sample is the homogenate of four or five aphids. Starch gel, stained with Fast Blue BB salt using 1-naphthyl acetate as substrate.

Fig. 2 Electrophoretogram showing variability of gene expression at the *est-4* locus between 16 individuals in one F₁ clone (TN 74) of *M. persicae*. Each sample is the homogenate of a single adult aphid. Individuals of the parent clone GCRJ-1 are placed at both ends of the gel for comparison. Starch gel, stained with Fast Blue BB salt using l-naphthyl acetate as substrate.

such as might occur if resistance-associated loci were close to the point of translocation, and thus liable to inactivation by repositioned heterochromatin. V-type position effects classically explain variations in gene expression between cells within an individual, but could apply equally to differences between individuals within a clone. The extent of variegation in any one clone would be subject to the influences of modifiers in the genetic background, so that in different F₁ clones the expression of genes subject to position effect could vary either within individuals or between individuals in a single generation, or changes could occur over many generations. Intracolonial variation due to V-type effects would clearly complicate the results of insecticide bioassays, and might explain the widely different LD₅₀ values obtained from translocated clones in the resistance tests in Japan (Table 2). It could also explain the instability of organophosphorus resistance within certain clones of *M. persicae*^{8,13-15}.

Further work is necessary to substantiate the position effect hypothesis. The variable activity of the *est-4* locus in translocated clones of *M. persicae* could prove a useful tool for studying certain aspects of gene expression.

We thank J. Martin and A. Sutton for technical assistance, and Drs M. Ashburner and G. Hewitt for commenting on the manuscript. We regret that there is insufficient space to thank individually all those who sent *M. persicae* to England for karyotyping.

Does carcinogenic potency correlate with mutagenic potency in the Ames assay?

AN approximately linear relationship between the mutagenic potency of a chemical in the *Salmonella* reverse mutation assay of Ames¹ and its carcinogenic potency in animals, was recently alluded to² and has since been discussed at several international symposia^{3,4}. The implications of such a claim are clearly momentous. At present, the fact that the *Salmonella* assay can give both false positive and false negative results when compared with animal tests^{6,7} has led to its being regarded as an early warning system rather than the final arbiter of animal and possibly human carcinogenicity. A correlation between mutagenic and carcinogenic potency would, however, mean that a strong positive response in the Ames assay would define a potentially potent carcinogen, and would suggest that some compounds give positive results in this assay but fail to induce cancer in animals because their mutagenic potency is too low. We believe, however, that there is sufficient experimental evidence to treat any superficial potency correlation with great caution at this stage.

Our reservations about this correlation are based on the following. The concept that it is the absorption, distribution, metabolic activation and resultant half life of derived active species, rather than the *in vitro* mutagenic potency of a compound which determines its carcinogenic potency has been discussed by others^{8,9}. Also, some compounds are known to display species-dependent biological (including carcinogenic) properties¹⁰, yet it is from such species-dependent carcinogenicity studies that a potency correlation would have to be derived. Thus, a compound may be potentially carcinogenic as defined by an *in vitro* test yet be non-carcinogenic in the particular strain of species of animal in which it has been evaluated.

Apart from the above concerns in *in vivo* animal studies, serious doubts can be raised about the implied absolute quantitative significance of a *Salmonella* assay revertant colony count. In most cases, compounds which are mutagenic and/or carcinogenic require metabolic activation before they can elicit their effect. The *in vitro* medium usually employed for this activation is a sub-fraction of an homogenate of induced rat liver, the S9 microsomal mix. Despite its efficiency in a general sense (activation against no activation), the results mediated by this preparation are not generally regarded as being quantitatively significant. Also, although the general method of preparation and use of the S9 mix has been described¹, individual variations in protocol detail are common¹¹. If the assay results mediated by an enzyme preparation are to be quantitatively assessed then the enzyme preparation itself should first be calibrated in terms of the presence and activity of at least some of the basic activation and deactivation enzymes.

This is rarely, if ever, undertaken. Similarly, liver enzyme inducing agents such as Aroclor 1254, phenobarbitone or methylcholanthrene are used specifically to increase the levels or activity of certain enzymes, but in general no attempt is made to either quantitate this increase or to assess if it invariably leads to an increased mutagenic response.

The quantitative problems posed by unquantified and uncalibrated enzyme preparations can be illustrated by several recent studies. The carcinogen benz(a)pyrene (Fig. 1, I) requires metabolic transformation before it can elicit a carcinogenic or mutagenic effect. Although initial studies implicated the 4,5-epoxide (Fig. 1, II) (the K-region epoxide) as the critical intermediate^{12,13}, recent studies indicate that it is probably the 7,8-diol-9,10-epoxide derivative (Fig. 1, III) which is the important chemical species in cancer induction^{12,14-16}. The 7,8-diol group itself probably arises by attack on an intermediate 7,8-epoxide by epoxide hydratase enzymes¹⁴. It is, therefore, clear that the S9 mix used to activate benz(a)pyrene in an *in vitro* assay will be required to possess both oxidative enzymes for epoxide formation (such as cytochrome P-450) and epoxide-destroying enzymes, such as epoxide hydratase. In addition, various glutathione-S-transferase enzymes will be present in the S-9 mix and may react with any epoxide groupings present. It should therefore be possible to manipulate the muta-

Fig. 1 Structures of test compounds.

genic response obtained for benz(a)pyrene in an *in vitro* test simply by varying the relative levels or activities of these three enzymes, and this is observed. Figure 2 shows the results obtained by Oesch *et al.* for benz(a)pyrene in the Ames assay^{17,18}. As expected, the addition of pure epoxide hydratase enzyme essentially abolished the mutagenic response while the chemical inhibition of this enzyme greatly enhanced the observed mutagenic response. Two factors are important here; first, both of the relevant enzymes are present but generally unquantified in the rat liver S9 preparations used for routine *in vitro* testing. Unsuspected variations in their levels or activities could dramatically alter the mutagenic potency observed for a compound competitively using these enzymes. Second, compound III is a poor substrate

Fig. 2 Benz(a)pyrene action in Ames assay. Adapted from Glatt *et al.*¹⁷ and Oesch *et al.*¹⁸.

for epoxide hydratase¹⁴, which means that the mutagenic potency variations observed by Oesch were probably arbitrarily associated with the K-region epoxide¹⁹. A study of a series of 37 polycyclic aromatic hydrocarbon carcinogens²⁰ also revealed the overall lack of a correlation between carcinogenic potency and mutagenic potency in the Ames assay for that particular series of compounds. Similar findings have also been obtained for a series of structurally related nitrosamines²¹, while Bartsch has reported that vinylidene dichloride (Fig. 1, IV) is mutagenic in the Ames assay when using mouse derived S9 but almost inactive when using rat derived S9²². In the latter situation it is important to consider which result would be the relevant one to quote quantitatively *vis-à-vis* any possible animal carcinogenicity data. Further, the possibility that rats may possess the ability to detoxify epoxides more efficiently than do mice may account for the fact that trichloroethylene produces tumours in mice but not in rats²⁰ (the fact that the carcinogenicity of trichloroethylene has been suggested to arise from the butene oxide stabiliser present in the material tested²⁴ does not alter this argument).

This raises the question as to whether potency correlations should be applied within a given species of animal (for example, comparing the mutagenic potency of a compound in the Ames assay using hamster derived S9, with carcinogenicity data also derived in hamsters). The dangers inherent in this practice have been vividly demonstrated by McGregor, who showed²⁵ that cotton rat derived S9 was the best of eight different liver preparations, variously derived from five different species of animal, for the mutagenic activation of acetylaminofluorene (Fig. 1, V) in the Ames assay. Nonetheless, the cotton rat is

Fig. 3 Mutagenic response of *S. typhimurium* TA 1538 to benz(a)pyrene using Aroclor 1254 induced (○) and uninduced (●) mouse liver S9 mix and Aroclor 1254 induced (△) and uninduced (▲) rat liver S9 mix. Bacteria were obtained from B. N. Ames. Induction and preparation of S9 mix according to Ames *et al.*¹. The experimental protocol followed in all of these experiments is the same as in our earlier studies⁷.

claimed to be resistant to acetylaminofluorene-induced cancer²⁵. A further consideration is the diet employed during a carcinogenicity study or in animals from which livers are to be obtained for an S9 homogenate. The induction of liver tumours in rats with butter yellow (Fig. 1, VI) is dependent on the levels of the deactivating azoreductase enzymes in their livers. By reducing riboflavin intake in the diet, the levels of the riboflavin-dependent azoreductase enzymes are lowered, with a corresponding increase in tumour yield (that is, an apparent increase in carcinogenic potency)²⁶. It would therefore be expected that in the S9 mix used to evaluate related azo-compounds in the Ames assay, the levels of these enzymes would be both variable (by design or by chance) and critical to the apparent mutagenic potency observed. Similar nutritionally induced variations in liver cytochrome P-450 levels, with a resultant variation in enzyme-mediated compound metabolism, have also been reported¹⁰.

In an attempt to demonstrate clearly the dangers of detailed extrapolation of data generated in an *in vitro* test to the possible *in vivo* situation, we conducted a series of experiments with benz(a)pyrene. Five separate S9 fractions were prepared from uninduced and induced rat liver (Sprague-Dawley, Alderley Park strain), induced and uninduced mouse liver (Alderley Park strain, albino) and uninduced guinea pig. The results obtained in the Ames assay using these S9 fractions are shown in Figs 3 and 4. The guinea pig S9 fraction is incapable of effectively activating benz(a)pyrene into a mutagen while both the rat and mouse liver S9 fractions are variously effective. Thus, in this case of benz(a)pyrene at least, induction of the mouse and rat liver enzymes resulted in a reduction rather than an increase in the observed mutagenic potency.

In the supernatant of the S9 fractions there are glutathione-S-transferase enzymes and other chemical species which could react with epoxide intermediates and thereby inactivate them as mutagens. To investigate this possibility we removed the supernatant material from the guinea pig S9 fraction, leaving a pure microsomal fraction (105,000g fraction), and retested benz(a)pyrene using these microsomes in place of the original S9 fraction. The resultant positive effect is shown in Fig. 5. It can be inferred that the supernatant material of the guinea pig S9 fraction contained epoxide-destroying species which had been masking the mutagenic effect of any microsomally derived epoxides. Finally, the same guinea pig supernatant material was added to the microsomes (105,000g fraction) derived from the initial mouse S9 fraction and the reconstituted mouse/

Fig. 4 Mutagenic response of *S. typhimurium* TA 1538 to benz(a)pyrene using S9 mix made from uninduced mouse liver (Δ) and uninduced guinea pig liver (\bullet).

Fig. 5 Mutagenic response of *S. typhimurium* TA 1538 to benz(a)pyrene using guinea pig liver microsomes (105,000g fraction) with added cofactors (\bullet) and uninduced mouse liver microsomes (105,000g fraction) with supernatant from guinea pig (30,000g fraction) and co-factors (Δ).

guinea pig S9 fraction used to re-evaluate benz(a)pyrene. As expected, a negative response was obtained (Fig. 5). Thus, by simple fractionation of the S9 mix, the initial guinea pig negative response and the initial mouse positive response for benz(a)pyrene were both capable of reversal. These results, which are admittedly somewhat contrived in terms of the S9 preparations used for their generation, cannot be discounted as irrelevant because any metabolic activation system is presently regarded as acceptable as long as it can produce a positive result for a chemical.

The above experiments demonstrate that both mouse and guinea pig microsomes are potentially able to activate benz(a)pyrene into a mutagen, but that in a routine assay the observed result is strongly influenced by the surroundings in which the activation occurs, in this case the supernatant fluid. In the context of such sensitivity it should be anticipated that significant variation will occur in any biological parameter, such as mutation or cancer induction, when *in vivo* and *in vitro* responses are compared. A new dimension has recently been added to this debate by the co-mutagenicity effects described by Sugimura *et al.*²⁷⁻²⁹. By testing carcinogens such as butter yellow (Fig. 1, VI) in the presence of the non-mutagens harman or norharman, the mutagenic potency observed for the carcinogen can be dramatically increased (up to 40-fold in one case)²⁸. Further, compounds such as aniline and *ortho*-toluidine showed mutagenic properties under these conditions while being negative in the normal Ames assay²⁹. Whatever the explanation for these observations, their effect on an apparent potency correlation could be critical.

The variations in observed mutagenic potency of a chemical in the Ames assay discussed above are in general limited within a 100-fold range, which may seem negligible to an assay which has a 10⁶-fold mutagenic potency range². In our laboratory, however, this assay only has a 10³-fold range of mutagenic potency⁷. The above mentioned variations are, therefore, highly significant. There are also a sufficient number of exceptions to a potency correlation to discourage its rapid acceptance. For example, the very weak carcinogen 9,10-dimethylanthracene (Fig. 1, VII) (ref. 30) is a potent mutagen in the Ames assay⁷. In contrast, the potent rat carcinogen hexamethylphosphoramide (Fig. 1, VIII) (ref. 31) is usually negative in this assay³², but is mutagenic as evidenced by a positive response given by this compound in *Drosophila*³³. The evaluation of potency correlations may be important when attempting to understand the mode of action and tissue or species specificity of individual carcinogens and mutagens^{34,35}. The premature acceptance of

an invariable correlation, however, may well reduce or at least impede the ultimate acceptance and beneficial impact of the Ames and related assays.

Metabolic deactivation of mutagens in the *Salmonella*-microsome test

THE *Salmonella typhimurium*/mammalian microsome test of Ames *et al.*¹ has provided a simple and sensitive short term assay for the detection of environmental mutagens. Moreover, there is excellent correlation between a positive reaction of the compounds so far tested in this prokaryotic test system and their carcinogenicity²⁻⁴. Metabolic activation of precarcinogens is achieved by incubating, on Petri dishes, the compounds to be tested, the bacterial strains and liver homogenates together with a NADPH generating system¹. The opposite phenomenon, that is conversion from mutagenically active to inert compounds, is also widely known to occur *in vivo*^{5,6} and inactivating enzymes have also been identified for some reactive metabolites⁷. However, the possibility of checking deactivation of the mutagenic potential of chemicals by means of the same *in vitro* system set up for metabolic activation has received little attention. The results reported here provide evidence that some compounds which are mutagenic *per se* for *S. typhimurium* can be partially or totally deactivated in the presence of liver homogenates. This possibility should be considered when results of the *Salmonella*/microsome assay are interpreted, and correlated with animal and epidemiological data.

The compounds tested were sodium azide, sodium dichromate and sodium nitrite (Merck), 5-nitro-2-furoic acid (Ega-Chemie), and captan (*N*-trichloromethylthio-tetrahydro-phtalimid) (Serva). 2-Aminofluorene (Ega-Chemie) was tested to check the activity of the rat microsomal preparation used. Solutions and

serial dilutions of compounds were made in water (sodium azide, dichromate and nitrite, and 5-nitro-2-furoic acid) or in dimethylsulphoxide (captan and 2-aminofluorene) and assayed by the plate incorporation test described by Ames *et al.*⁸. TA100 was used as bacterial tester strain. All assays were carried out in the absence and in the presence of the liver microsomal fraction (S-9 fraction) prepared from rats induced with a polychlorinated biphenyl mixture (Aroclor 1254, Monsanto), mixed in various amounts (10-50 µl per plate) with a fixed amount (0.5 ml per plate) of a NADPH-generating system (S-9 mix).

As shown in Table 1, 2-aminofluorene was mutagenic for strain TA100 of *S. typhimurium*, but only after addition of the liver microsomal preparation, while the other compounds were mutagenic *per se*, with dose-response effects. However, addition of the S-9 mix, containing 50 µl of S-9 fraction, resulted in a significant decrease of revertant colonies. The loss of mutagenic response was complete when test compounds were given at low doses, while larger amounts exceeded the deactivating capacity of the S-9 mixture used, with the exception of sodium

Table 2 Relationship between the amount of S-9 fraction embedded in the soft agar overlay and the number of TA100 revertants induced by mutagenic compounds

Compound	Amount per plate (µg)	Amount of S-9 fraction per plate (µl)						
		0	10	20	30	40	50	
Controls	0	234	241	215	223	218	209	
2-Aminofluorene	20	216	325	810	1,430	1,725	2,095	
Sodium dichromate	40	705	420	370	283	228	221	
Sodium azide	1	645	397	302	251	234	237	
Sodium nitrite	5,000	568	454	396	361	358	341	
Captan	2	845	570	436	390	327	296	
5-Nitro-2-furoic acid	20	1,035	640	529	451	385	337	

dichromate, which was totally deactivated below toxic concentrations. The metabolic deactivation of the compounds tested, as well as the metabolic activation of 2-aminofluorene, was correlated with the amounts of liver microsomal fraction embedded in the soft agar overlay (Table 2). Conversely, the number of revertants was not significantly affected by addition of S-9 cofactors without microsomal fraction.

Of the compounds studied, sodium azide, sodium nitrite, captan and 5-nitro-2-furoic acid had been included in the group of 'false' positive mutagens^{2,3}, that is of chemicals which were found to be mutagenic for *S. typhimurium* and gave negative or ambiguous results in animal tests. The reduction of the mutagenic activity in the *Salmonella* test system, in the presence of liver microsomal fractions, might account for the discrepancies between these *in vitro* and *in vivo* findings. Similarly, sodium dichromate and other hexavalent chromium compounds were associated with an increased incidence of lung cancer in man^{9,10} and were generally positive in animal assays, by inducing tumours at implant sites¹¹.

Further investigations are needed to elucidate the metabolic pathways leading to conversion of mutagenically active compounds into inactive metabolites. Use of microsomal fractions from various human or rat tissues should be helpful in assessing an appropriate correlation with epidemiological and animal data. The results of an extensive study of hexavalent chromium mutagenicity¹² suggest, for instance, that the metabolic deactivation of the metal by liver preparations is due to reduction to the trivalent form. In contrast to the hexavalent form, trivalent chromium is neither toxic nor mutagenic for *S. typhimurium*¹³ or *Escherichia coli*¹⁴. Interestingly, such conversion apparently also occurs in human erythrocytes, while rat lung and muscle microsomal fractions do not affect the mutagenicity of hexavalent chromium¹².

Biochemical characterisation of stages of hepatocarcinogenesis after a single dose of diethylnitrosamine

CURRENT understanding of the pathogenesis of neoplasia rests principally on the demonstration¹⁻³ that the induction of carcinomas of mouse skin by hydrocarbons can be separated into at least two stages. There is evidence of similar stages in the natural history of carcinogenesis of nonepidermal tissues⁴⁻⁷. For example, Peraino *et al.*⁸ have shown that short term feeding of acetylaminofluorene to rats followed by a long term diet containing 0.05% phenobarbital results in 100% incidence of hepatomas, whereas animals receiving acetylaminofluorene and no phenobarbital developed 10 times fewer hepatocarcinomas. Peraino's procedure and that of Kitagawa *et al.*⁷, who fed rats azo dye followed by phenobarbital, required that the

Table 1 Effect of phenobarbital fed to rats given diethylnitrosamine after partial hepatectomy

Treatment	No. of enzyme-altered foci per cm ² liver at 8 months	Hepatomas
0.05% Phenobarbital (5)	0	0
DEN + PH (6)	3,370 ± 200	0
DEN + PH + 0.05% phenobarbital (8)	18,500 ± 900	7

Rats were partially hepatectomised (PH) and diethylnitrosamine (10 mg per kg) was administered as before⁸. Two months later one group receiving diethylnitrosamine and a control group were fed 0.05% phenobarbital with standard laboratory chow for a subsequent 6 months. The third group continued to receive the chow diet for the remainder of the experiment. At the end of this time animals were killed and sections of the liver were removed and frozen on solid CO₂. Serial sections of the frozen blocks of hepatic tissue were cut and stained consecutively with haematoxylin and eosin and for glucose-6-phosphatase¹⁰, canalicular ATPase⁹ and γ -glutamyl transpeptidase¹². Photographs were taken of each stained section and the number of enzyme-altered foci on each section was determined from tracings using transparent plastic. By appropriate overlaying of the three transparencies, one for each stain, the total number of enzyme altered foci could be calculated by the procedure of Scherer *et al.*²⁰.

carcinogen be fed to the rats for 3-8 weeks. On the other hand, Scherer and Emmelot⁸ have shown that a single large dose of diethylnitrosamine given to rats within 24 h of partial hepatectomy can induce hepatocellular carcinomas, whereas low doses (< 30 mg kg⁻¹), given in the same way, give rise only to small foci of cells deficient in ATPase, comparable with those described earlier^{9,10}. Further, Solt and Farber¹¹ have reported that a single dose of diethylnitrosamine followed by acetylaminofluorene and partial hepatectomy rapidly produces foci containing γ -glutamyl transpeptidase, in contrast to the situation in normal liver which exhibits no histochemical activity of that enzyme. By combining the procedure of Scherer and Emmelot⁸ with that of Peraino *et al.*⁸, we have been able to distinguish clearly between two stages in the genesis of liver cancer in rats.

We used the method of Scherer and Emmelot⁸ followed by the regimen of Peraino *et al.*⁸ (Fig. 1). The results are shown in Table 1. Unlike previous studies^{8,10}, ours involved the scoring of enzyme-altered foci in serial frozen sections by means of stains for three different enzymes: glucose-6-phosphatase¹⁰, canalicular ATPase⁹ and γ -glutamyl transpeptidase¹². In accord with the earlier studies^{8,11}, we found foci exhibiting a deficiency of glucose-6-phosphatase and/or canalicular ATPase as well as a positive stain for γ -glutamyl transpeptidase alone

Fig. 1 Schematic representation of the protocol used for the induction of enzyme-altered foci and carcinomas in rats given a single dose of diethylnitrosamine (DEN, 10 mg per kg) by intubation 24 h after partial hepatectomy (PH)⁸. Eight weeks later a group of these animals was placed on a diet containing 0.05% phenobarbital (indicated by shading), while the other group received the same diet containing no drug. A control group was fed 0.05% phenobarbital during the same period. In all experiments female Sprague-Dawley rats weighing 200-220 g were used.

or in combination with a deficiency of one or both of glucose-6-phosphatase and ATPase (Table 2). Phenobarbital alone, even after 6 months, produced no enzyme-altered foci. But when administered for 6 months, after a 2-month interval following partial hepatectomy plus diethylnitrosamine (5–10 mg per kg), this drug caused a six- to eightfold increase of enzyme-altered foci and most animals had hepatocellular carcinomas. Evidence that such enzyme-altered foci represent an early clonal stage in the development of hepatocellular carcinomas has been presented before^{9,13,14}, suggesting that in hepatocarcinogenesis it is possible to identify histochemically the immediate progeny of the putative initiated cells.

On the basis of earlier studies^{15,16}, we established the biochemical phenotype of each enzyme-altered focus using a suitable combination of overlay transparencies traced from photographs of three serial sections, each obtained for one of the enzymes in question. Figure 2 shows a typical composite overlay with different symbols for each area exhibiting one or more enzyme alteration(s). It was prepared from the liver of an animal given diethylnitrosamine (10 mg per kg) 24 h after partial hepatectomy followed by a 6-month dietary regimen of 0.05% phenobarbital. Extremely heterogeneous small foci and two larger foci of microscopic hepatocellular carcinomas can be seen. The phenotypic heterogeneity is analogous to that seen in both primary and transplanted hepatocellular carcinomas in rats¹⁵. Other studies have demonstrated that hepatocellular carcinomas are heterogeneous for both glucose-6-phosphatase¹⁷ and γ -glutamyl transpeptidase¹⁸.

By this technique, we counted the enzyme-altered foci of each of the seven possible phenotypes (Table 2). In animals given diethylnitrosamine alone, more than 75% of all foci exhibited only a single enzyme alteration with roughly equal frequency. In contrast, 45% of foci in the livers of animals given carcinogen followed by phenobarbital in their diet exhibited γ -glutamyl transpeptidase whereas 30% were equally distributed between those exhibiting ATPase deficiency alone and those exhibiting this deficiency in the presence of γ -glutamyl transpeptidase. The relative proportion of foci exhibiting defects of all three enzymes increased more than twice over that in the animals given the carcinogen only.

Fig. 2 Biochemical phenotypes of enzyme-altered foci in three serial sections of liver from a rat given a single dose (10 mg kg⁻¹) of diethylnitrosamine 24 h after partial hepatectomy followed 2 months later by feeding 0.05% phenobarbital for a subsequent 6 months. Each area is outlined to represent the enzyme alteration exhibited in that region as follows: 0-0-0, glucose-6-phosphatase-deficient areas; - - - - -, ATPase-deficient area; γ -glutamyl transpeptidase present in area. In areas exhibiting more than one enzyme alteration, composite and/or parallel symbols are used. The figure was obtained by overlaying three separate transparencies after tracing on each of the outlines of areas exhibiting one enzyme alteration. Although in some areas not all cells in the focus exhibited the same phenotype, the area was scored as having the phenotype (Table 2) of most of the cells therein.

The mechanism by which the phenotypic heterogeneity of the foci is produced is not clear. In hepatocellular carcinomas this heterogeneity has been suggested to result from alterations in messenger RNA template stability¹⁵. If the phenotypic heterogeneity evident in enzyme-altered foci, the earliest discernible putative precursor of the hepatocellular carcinoma, reflects the phenotypes of the fully developed hepatocellular carcinoma, one may suggest that such biochemical changes

Table 2 Number and phenotypes of enzyme-altered foci per g of liver

	GP, AP, GT	GP, GT	GP, AP	AP, GT	AP	GT	GP	Total
DEN + PH	120±80 (3.6)	100±50 (3.0)	300±170 (8.9)	170±80 (5.0)	930±400 (27.6)	750±250 (22.3)	1,000±400 (29.7)	3,370±200 (100)
DEN + PH + 0.05% phenobarbital	1,450±300 (8.1)	300±100 (1.7)	700±250 (3.9)	2,700±700 (15.1)	2,700±700 (15.1)	8,700±1,100 (44.8)	2,000±500 (11.2)	18,550±900 (100)

GP, glucose-6-phosphatase negative; AP, canalicular ATPase negative; GT, γ -glutamyl transpeptidase positive; DEN, diethylnitrosamine; PH, partial hepatectomy.

Numbers in parentheses represent the percentage distribution of the foci in these conditions.

Five rats given DEN + PH alone and eight rats given DEN + PH + phenobarbital were used for these calculations. See text and Table 1 for further details.

These results show that two distinct stages can occur in hepatocarcinogenesis in analogy to that seen in skin. It is not clear how the promoting agent increases the number of enzyme altered foci; however, this system may be the first in which the immediate progeny of the putative initiated cells have been identified. Possibly, promoting agents not only cause the biological expression of malignancy but also stimulate the replication of dormant initiated cells, which in the absence of the promoter would not have proliferated. If each enzyme-altered focus is a clone derived from such a cell¹⁴, approximately one in 10⁴–10⁵ cells in the liver seem to be initiated by diethylnitrosamine as expressed after feeding with phenobarbital.

The production of enzyme altered foci in the liver may be a general result of hepatocarcinogen administration. Studies from our laboratory (unpublished) as well as those of Pugh and Goldfarb¹⁹ have demonstrated enzyme-altered foci following the administration of azo dyes and acetylaminofluorene to rats.

occur at or shortly after the process of initiation and remain relatively constant throughout the development of a malignant tumour from an initiated cell population.

Myeloid colony-forming cells express human B lymphocyte antigens

STUDIES in experimental animals suggest that lymphoid and myeloid cells share a common stem-cell precursor¹, but human lymphoid-myeloid stem cells have been difficult to document. Indirect evidence for such cells has come from recent observations that human B lymphocyte antigens occur not only on B lymphocytes but also on monocytes and leukaemic myeloblasts²⁻⁶. If normal immature myeloid cells, like leukaemic myeloblasts, share a common differentiation antigen with B lymphocytes, it would seem even more likely that myeloid cells and B lymphocytes share a common stem-cell precursor. We have therefore compared the ability of bone marrow cells to form macrophage-granulocyte colonies *in vitro* after complement-mediated lysis of cells expressing either human B-lymphocyte antigens (HLA) or human T-lymphocyte antigens (HTLA). Our results show that macrophage-granulocyte colony-forming cells (CFU-C) express HBLA but not HTLA antigens.

Ficoll-Hypaque separated mononuclear cells were obtained from bone marrows of children with acute leukaemia or lymphoma in remission. These cell suspensions were depleted of HBLA⁺ or HTLA⁺ cells by treatment with rabbit anti-HBLA or anti-HTLA plus complement (the preparation and specificity of these antisera have been described in detail previously⁷). The viable cells remaining were incubated in methylcellulose with leukocyte-conditioned medium and examined for macrophage-granulocyte colonies after 10 d in culture.

The results of experiments using bone marrow cells from four different subjects are shown in Fig. 1. In every case, compared with control cells preincubated with normal rabbit serum + C, incubation of the marrow cells with anti-HBLA + C before culture resulted in a marked reduction in numbers of colonies formed on day 10. Incubation of cells with anti-HTLA + C, however, resulted, if anything, in an increase in colony numbers on day 10 of culture. Thus the myeloid precursor cells capable of forming macrophage-granulocyte colonies *in vitro* seem to express HBLA but not HTLA antigens. We have been unable to detect HBLA antigens by immunofluorescence or complement-dependent cytotoxicity on mature peripheral blood granulocytes (J.K., unpublished observations). These findings are consistent with recent observations by Ross *et al.*⁸ that rabbit antisera to purified lymphocyte membrane components detect B-lymphocyte antigens on normal bone marrow myeloblasts and myelocytes but not on metamyelocytes, band forms or mature granulocytes.

That B lymphocytes and immature myeloid cells share common antigens supports the concept that lymphoid and myeloid cells arise from a common stem-cell precursor. The fact, however, that T lymphocytes and even relatively im-

Fig. 1 Effect of complement-mediated lysis of HBLA⁺ or HTLA⁺ bone marrow cells on *in vitro* macrophage-granulocyte colony formation. Suspensions containing 10^7 cells ml^{-1} diluent (RPMI) 1640 (with 20% foetal calf serum) were incubated for 60 min at 37°C with equal volumes of 1:10 diluted heat-inactivated rabbit anti-HTLA or anti-HBLA and complement (fresh normal rabbit serum). Control cells were incubated with heat-inactivated normal rabbit serum and complement. After determining the percentage viability by Trypan blue exclusion, the cells were washed three times and the cell concentration adjusted to 1×10^5 viable cells ml^{-1} alpha-media. The cells were cultured for 10 d in 1% methylcellulose in quadruplicate plates as described previously¹³ using leukocyte-conditioned medium at a 20% concentration (v/v) as the source of stimulators. Open columns, normal rabbit serum + complement; hatched columns, anti-HTLA + complement; solid columns, anti-HBLA + complement.

mature T-cell precursors⁸, lack HBLA antigens raises the question of whether the stem cells for T lymphocytes are distinct from the stem-cell precursors of B lymphocytes and myeloid cells. Recent observations that terminal transferase (TdT), an enzyme normally found only in thymocytes and a small population of immature bone marrow cells⁹⁻¹¹, occurs in HBLA⁺ as well as HTLA⁺ leukaemic lymphoblasts (J.K., unpublished data) and in some leukaemic myeloblasts¹² mitigates against this possibility and suggests instead that T cells, B cells and myeloid cells all share a TdT⁺ stem-cell precursor. From the present findings it would seem likely that such a stem cell also expresses HBLA antigens which are lost at a prethymic stage of T-cell differentiation, just as they are lost at a metamyelocyte stage of granulocyte differentiation. Attempts to test this model of leukopoiesis further would be facilitated by the availability of improved methods for the detection and isolation of human lymphoid-myeloid stem cells. Antisera to HBLA antigens could be useful tools in such endeavours.

Stable variants affecting B cell alloantigens in human lymphoid cells

THE human major histocompatibility complex (MHC) is defined by four loci: *HLA-A*, *B* and *C* are serologically defined and *HLA-D* was initially defined by the mixed lymphocyte reaction (MLR)¹. There is now evidence that a group of HLA-linked, serologically defined B cell-specific alloantigens are the gene products of either the *D* locus itself or of closely linked genes^{2,3}. Strong associations are seen between alleles of *HLA-D* and the B cell-specific genotypes, and B cell antisera inhibit the MLR^{4,5}. The *D*-associated antigens differ from the products of *HLA-A*, *B* and *C* in chemical structure and in tissue distribution⁶. Human B-cell alloantigens resemble Ia antigens in mice. Analysis of the relationships among Ia antigens, MLC loci and other functions mapping in the I region is limited in both humans and mice by the availability of recombinant individuals⁷. Because such recombinants are rare, we have begun an analysis of this region by mutation⁸, using immunoselection to isolate mutants defective for MHC gene products in human lymphoid cell lines. We describe here the first Ia variants to be isolated and characterised in any species.

The B cell-specific alloantibodies used for selection of the variants were isolated from antiserum 0800 (Associated Bio-medical), which also contained antibodies against HLA-B8. This antiserum reacted with some non-B-8 cells when tested on B-cell lymphoid lines. UM21, a non-B-8 cell line which reacted with 0800, was used to absorb the non-HLA-8 antibody, which was then eluted from the cells by incubation for 30 min at 0 °C in glycine-HCl-saline buffer pH 3.0, 0.5 M. This material is referred to as 0800 eluate (0800E). 0800E has the properties of B cell antibody⁹: first, in individuals reactive with 0800E, 10-15% of PBLs were labelled by indirect immunofluorescence; second, after separation of lymphocyte subpopulations from reactive individuals by anti-F(ab) column or sheep red blood cell (SRBC) rosettes, the B cell-enriched fraction gave 60-65%

positive cells and the T-cell fraction <1% positive cells; third, fowl anti-β2 microglobulin, which blocks the cytotoxic activity of alloantisera to HLA-A, B and C but not of B cell-specific antibody¹⁰, reduced the titre of 4 A and B alloantisera on sensitive target cells, but did not alter the cytotoxicity of 0800E. The 0800E reacted with 4 of 17 B-cell lines and neither of 2 T-cell lines. Thirteen of the B-cell lines were also tested with 169 B-cell alloantisera of the 7th Histocompatibility Workshop (7WS) panel¹¹, and 0800E showed correlation with the antiserum cluster WIA1 (Table 1).

Table 2 Cytotoxicity titres of B cell-specific sera, HLA sera and anti-β2-microglobulin sera

	Wild type progenitor T5-1	Variants (6.1.6) (8.1.6)
B cell-specific alloantisera		
0800 eluate	4	< 1
277	2	< 1
HLA-A and B alloantisera*		
HLA-B8		
0800 absorbed	16	8
CAMPBELL	4-8	4
CHAYRA	2	2
HLA-B27	16-32	16
HLA-A2 (R3 absorbed rabbit heterosera)	8-16	8
HLA-A1		
SHILEY	4-8	4-8
B cell-specific heterosera		
814	128	8-16
Anti-55	64-128	4-8
Anti-23-30	400-800	< 1
R20 (anti-T5-1, absorbed with 6.1.6)	16-32	< 1
Anti-β2 microglobulin (rabbit)	256-512	256

All antisera were tested for cytotoxicity by the Terasaki method. Doubling dilutions were made in human AB sera (except for anti-β2-microglobulin where RPMI 1640 was used) and pooled rabbit complement which had been absorbed with T5-1 cells was used. The titre of a serum on a cell line is the highest dilution giving 50% kill.

*Alloantisera except where otherwise noted; HLA antisera for HLA-A2, B8 and B27 are described elsewhere¹².

The cell line used in the selection was T5-1, which has been used in previous studies on HLA variants¹². T5-1 has a pseudo-diploid karyotype and HLA haplotypes *HLA-A1*, *B8* and *HLA-A2*, *B27*, *CW1*. With respect to B cell-specific alloantigens, the cell line reacts with all sera in clusters defining WIA1 and WIA3, which seem to be alleles of a single locus¹¹.

Before selection, T5-1 was mutagenised as described previously¹¹ to increase the frequency of variants. Logarithmically growing cells were suspended in either 4 μg ml⁻¹ ICR-191 or 50-100 μg ml⁻¹ ethylmethanesulphonate (EMS) for 24 h. After washing twice and resuspending in fresh medium, the cells were cultured until the viability was ≥80% as measured by Trypan blue exclusion. For the selection of variants, 2.5-5.0×10⁵ cells were incubated in 0.1 ml antiserum for 45 min at 22 °C, centrifuged and then exposed to pooled absorbed R C' in excess for 90 min at 37 °C, washed and then plated in soft agarose⁸. Surviving clones were isolated approximately 14 d later and tested with 0800E. Among a total 1×10⁶ cells treated with ICR-191 and selected against, a single 0800E-resistant clone was found (6.1.6). Another aliquot of the same ICR-191-treated cells gave 22 HLA-B27 variants for every 10⁶ cells selected. Two 0800E-resistant clones (8.1.6 and 8.2.6) were recovered from 2.5×10⁵ EMS-treated cells; another aliquot of these cells gave 24 B27 variants per 2.5×10⁵ cells.

Resistant clones 6.1.6 and 8.1.6 were tested with the selecting antiserum at least five times over a period of 6 months of cultivation in normal medium (a total of ≥80 population doublings) and the phenotype was stable. Cytotoxicity assays with a panel of A and B antisera (Table 2) showed that the variants were essentially unaltered in expression of HLA-1, 2, 27 and 8.

To define the nature of the antigenic loss further, the variants were tested with the 169 B cell-specific (Ia) 7WS alloantisera (Table 3) and with several rabbit sera prepared against partially purified human Ia. Variant 6.1.6 has lost reactivity with both WIA1 (4/4 sera) and WIA3 (5/5 sera) and, in fact showed no reactivity with any of the 44 sera that defined antigenic clusters. Of 58 sera that reacted with T5-1, only one weak reaction was retained, and this was with a serum which

also reacted with a T-cell line. In addition to the loss of alloantigenic determinants, 6.1.6 seems to have lost the constant portions of the Ia molecule as indicated by nonreactivity with anti-P23, 30 (ref. 6), a heteroantiserum prepared against papain solubilised, purified B cell-specific glycoprotein, which has a titre of 200–400 against T5-1. Antiserum 814¹³ and anti-55 (A. Fuks, unpublished) are antisera against immunogens prepared by detergent solubilisation and partial purification of the alloantigen-bearing glycoprotein dimer from two different B-cell lines and both showed reductions in titre (from 128 to 8–16 and from 64–128 to 4–8 respectively (Table 2)). In each case, this residual reactivity was approximately equal to that seen against the T-cell line HSB-2.

To demonstrate that the nonreactivity of 6.1.6 with anti-23-30 was not due to nonspecific masking of the antigen, deoxycholate was used to lyse cells and solubilise membrane glycoproteins from T5-1 and 6.1.6, and the lysates were tested for antibody-binding according to the method of Reif^{14,15}. In three experiments wild-type cells gave an average *g* value, that is, number of cells to absorb one half of cytotoxic antibody, equal to 2.1×10^3 cells/ λ , but in each experiment lysates from 6.1.6 bound no antibody at cell levels equivalent to 1.68×10^5 cells. Thus the amount of antigen in 6.1.6 is $< 1/80$ of that of the wild type.

Further evidence that 6.1.6 had undergone loss of the constant portion of Ia came from absorption experiments in which rabbit antiserum raised against T5-1 was absorbed with 6.1.6. The absorbed antiserum was tested for reactivity with cell lines and on B and T cells from peripheral blood (Table 4). This absorbed antiserum should be specific for determinants missing in the variant¹⁸. The absorbed antiserum reacted with T5-1 and with all B-lymphoid lines with approximately equal cytotoxicity titres but with neither of the two

T cell lines. Moreover, the absorbed antiserum reacted with titres of 8 to 16 on separated B lymphocytes from three individuals but it gave no cytotoxicity with the T lymphocytes. Thus heteroantiserum made against T5-1 and absorbed with 6.1.6 recognises determinants present on B cells of all 18 individuals tested but not on T cells, consistent with the interpretation that 6.1.6 had lost the common portion of Ia.

The variant 8.1.6, also selected as resistant to the 0800E, has a more limited lesion; it was indistinguishable from wild type with the heterosera described above. Tested with the 7WS panel, it showed loss of reactivity for WIA1 (4/4 sera) but unaltered reactivity for WIA3 (5/5 sera) (Table 3). The variant thus has an alteration in the WIA1 allele. Among the sera other than those mono- and multispecific sera recognising defined specificities, seven sera (our designation UW-X) react with T5-1 but not with 8.1.6. These 'UW-X' sera also react with WIA1 and WIA2 among our B-cell lines. The UW-X sera may represent polyspecific sera (which react only with IA-1 in T5-1) or they may detect a public specificity which is shared by IA1, -2, and -6 and which is included in the 8.1.6 lesion.

Table 4 Cytotoxicity titres of rabbit heterosera prepared against T5-1 (progenitor) and absorbed with variants

		Anti-T5-1 absorbed with 6.1.6		absorbed with 8.1.6
		6.1.6	8.1.6	
T5-1	10.2.5	16–32	4	
	6.1.6	<1	—	
	8.1.6	16–32	4	
15 Unrelated B cell lymphoid lines*		4–8	—	
T cell lines				
	8402	<1	—	
	HSB-2	<1	—	
Peripheral blood lymphocytes (3 donors)				
	B-cell fraction†	8–16	—	
	T-cell fraction†	<1	—	

Fixed volumes of antisera were absorbed with varying numbers of variant cells to attempt to find a minimal number which would remove all cytotoxicity against the variant. Data shown are for antisera absorbed with 1×10^6 cells λ^{-1} .

*The other B lymphoid lines tested were 8866, BREL, ORI, BRISTOL 8, UM-21, DAUDI, HUP-2, SB-1, SC-LA, SC-TA, SC-JB, SC-BM, SC-CA, SC-AM, RAJI, and two T-cell lines HSB-2, 8402.

†Peripheral blood lymphocytes were fractionated on an anti-F(ab) column. B-cell fractions contained 94–96% s Ig-positive cells and T-cell fractions contained 1–6 s Ig positive cells. — = not done.

The two variants, both selected with the same antiserum, thus have different properties from one another. This is consistent with evidence previously obtained^{11,17} that the antiserum selects pre-existing variants rather than inducing modulation of the reactive antigen. 8.1.6 seems to have lost the WIA1 determinant but has retained the WIA3 determinant as well as the 'common portion' of the molecule, as determined by reactivity with the heterosera. In this respect 8.1.6 seems analogous to most of the A and B variants previously isolated. 6.1.6 is altered not only for the WIA1 alloantigenic determinant selected against but also does not express the allelic determinant WIA3 nor any 'constant portion' of the HLA-linked B cell specific glycoprotein as judged by two independent lines of evidence; first, the absence of antibody-binding from anti-23, 30¹⁸ by 6.1.6 whole cells or lysates, and, second, rabbit anti-T5-1 absorbed with 6.1.6 reacts with all B cells tested but with none of the T cells. 6.1.6 could be explained by a single mutation in a regulatory locus or by mutations in two structural genes or by an epigenetic event. Although 6.1.6 lacks both WIA1 and WIA3, the phenotype is unlikely to be the result of two mutations, one in each of the genes carrying these determinants because the frequency of such an event would be the square of the single event and no single mutants were observed among the ICR-191-tested cells. If 6.1.6 is due to a change in a

The sera of 7WS have been grouped into clusters defining eight groups. Results are shown for sera in clusters WIA1, WIA3, WIA6+3, WIA6+2+1 and a group of sera UW-X. Not shown are results for those clusters which gave a negative reaction pattern on both T5-1 and its variants. (Clusters WIA2, 4, 5, 7, 8, WIA A, IA4×7.) UW-X is the group of sera which react with T5-1 and are altered in the variant 8.1.6. (Analysis of UW-X on normal unrelated cell lines showed caucasian derived lines with either WIA1 or WIA2 were reactive; also reactive were two non-caucasian-derived lines, Daudi (African Black) and SJ-AH (Japanese), which are not WIA1 or WIA2. For discussion of nature of UW-X, see text.)

*Methods for cytotoxicity tests as in Table 2. Scores are means of two tests of undiluted antibody; values 2, 3, 4 indicate consistent positive reactions of increasing strength. —, Score ≤ 1.5 .

†Cases in which difference in score between replicates ≥ 2 .

regulatory locus, it is not associated with a switch to expression of a different alloantigenic allele detectable by alloantisera or by absorbed rabbit antisera. The possibility that 6.1.6 arose by an epigenetic event is an open one unlike previously described variants for HLA-A and B where there is a preponderance of evidence for the variants being the products of single gene mutations^{8,11,17}. Regardless of the nature of the 6.1.6 lesion, it is clear from the unchanged expression of HLA-A and B that it does not affect these other MHC-coded membrane glycoproteins.

The typing of alloantigenic variants such as 8.1.6, delineates Ia specificities in a manner which is independent from the conventional delineation by pedigree analysis. If the human Ia system resembles murine Ia in being composed of several tightly linked loci, the mutational approach should make this apparent by distinguishing the products of independent loci whereas pedigree analysis would require the discovery of rare recombinants. In the case of 8.1.6 the fact that reactions with five WIA1 sera were altered coordinately suggests that these sera probably are all reactive with the products of the same single locus. Ia variants should also be useful in exploring other questions such as the nature of the determinants which stimulate in the MLC and the regulation of Ia expression.

We are grateful for gifts of antisera from R. Winchester (heterosera 814 and allosera 277); A. Fuks, J. Kaufman and J. Strominger (heterosera anti-55 and anti-23, 30); P. Goodfellow (fowl anti- β 2m sera). We thank J. Sullivan for pairs of T and B cells, J. Callis for cell analysis by microfluorimetry, and Penny Bowman and Carl Soderland for technical assistance. Production *in vitro* of murine antibody to a human histocompatibility alloantigen

AN *in vitro* culture system from our laboratory which may be used to generate homogeneous antibodies to human cell surface antigens has been recently described¹. Using this system, we have obtained series of antibodies which discriminate between closely related human cells¹ and cell lines². The present report defines more precisely the potential of this system by showing how it may be used to obtain antibodies to a human cell surface antigen of well-defined specificity, the histocompatibility alloantigen HLA-A2.

The mouse spleen fragment culture system involves injecting limited numbers of donor spleen cells, with immunogen, into irradiated, syngeneic recipients; the recipient spleens are diced

into 1-mm³ fragments, which are cultured individually. The dose of donor cells is adjusted so that each fragment receives at most a few antibody-forming cell precursors which recognise the immunogen; these precursors proliferate during the culture period, and the antibody produced by the daughter cells is secreted into the culture medium^{1,3}. In the present study, the A2⁺ human lymphoblastoid cell line 8866 (ref. 4) was used as the immunogen, and the culture fluids from 167 fragments were studied. A radioimmunoassay^{2,5} was used to measure the antibody-binding activity of each fluid against both 8866 and an A2⁻ variant of that line, subline 1-2. This variant was isolated by immunoselection with an allogeneic anti-A2 antiserum, and lacks both cell surface and internal A2^{1,6,7}. We found that 141/167 fluids contained antibody to 8866, and all but three of these showed identical binding to that cell and its A2⁻ variant. The three remaining fluids, B9, F4 and H4, showed significantly greater binding to the A2⁺ cell (Fig. 1a-c).

Fig. 1 Binding of discriminator culture fluids to A2⁺ and A2⁻ cell lines. Antibody binding activity in culture fluids was assessed by radioimmunoassay. Generation of culture fluids: 10⁷ viable donor spleen cells were given intravenously to each of four lethally irradiated recipient mice; a few minutes later, 10⁷ 8866 cells were given intravenously to each recipient; 18 h later, recipient spleens were diced into 1 mm³ fragments and the fragments were cultured individually in 96-well plastic plates for 4 weeks, during which time the culture fluids were collected and replaced with fresh medium every 3-4 d. Donor mice were (BALB/c × C57BL/6) F1 mice that had received intraperitoneal injections of 10⁷ 8866 cells 15, 9, and 6 weeks before use. Recipient mice were F1 mice that had received a single intraperitoneal injection of 10⁷ 8866 cells 5 weeks before use. Radioimmunoassay: 25 μ l of culture fluid was incubated for 2 h at room temperature with 2 times 10⁵ glutaraldehyde-fixed target cells; target cells were washed extensively, and then incubated with 10 μ l ¹²⁵I-goat anti-mouse κ (30,000 c.p.m./10 μ l) (ref. 2) for 18 h at 4°C; the cell pellets were washed extensively, dried, and counted in a γ counter. Graphs show (counts bound with test fluid) - (mean of counts bound with eight control fluids). Control fluids were generated by culturing fragments from spleens which had received neither donor cells nor antigen. Mean control binding for each cell type: 8866, 188; 1-2, 214; T5-1, 211; 6.6.5, 202. a-c, Binding activity to 8866 (●) and variant 1-2 (○); d-f, binding activity to T5-1 (●) and variant 6.6.5 (○). Fluids F4 and B9: fluids collected after 7 and 10 d of culture were pooled for assay; a later collection (after 14 d) showed similar discrimination between A2⁺ and A2⁻ cell lines (not shown). Fluid H4: assays were performed on 14-d collection; an earlier collection also showed discrimination, but less overall activity (not shown). a and d, Fluid B9; b and e, fluid F4; c and f, fluid H4.

The specificity of the three discriminator fluids was verified in two ways; first, the radioimmunoassay was used to show that each of the three fluids also discriminated between a second A2⁺ cell line, T5-1, and an A2⁻ variant of that line, subline 6.6.5 (ref. 8) (Fig. 1*d-f*); second, a cytotoxic assay was used to assess the specificity of the fluids with respect to normal human peripheral blood lymphocytes (PBL). Each of the three fluids was cytotoxic for 2/2 A2⁺, A28⁻ PBL, and negative for 2/2 A2⁻, A28⁻ PBL (data not shown). Fluids B9 and F4 were also tested in a more extensive typing panel (Table 1), which confirmed that both fluids recognised A2⁺ cells, as well as cells bearing the highly cross-reactive⁹ specificity A28. Neither fluid

Table 1 Cytotoxic activity of discriminator fluids against normal human PBL.

Test cells	Fluid B9		Fluid F4	
	Sample 1*	Sample 2†	Sample 1*	Sample 2†
A2 ⁺ , A28 ⁻	13/13	14/14	12/13	2/2
A2 ⁻ , A28 ⁺	6/7	12/12	5/7	2/2
A2 ⁻ , A28 ⁻	0/10‡	0/19§	0/10‡	0/2

Cytotoxic testing was performed in plastic typing trays, using PBL labelled with fluorescein diacetate (FDA): 2,500 cells in 1 µl were incubated with 1 µl of culture fluid for 30 min at room temperature, after which 5 µl of fresh frozen rabbit serum was added; cell viability was determined after an additional room temperature incubation for 2h 30 min. Table shows the ratio of target cells showing strong positive reactions to target cells tested.

*Fluids collected after 7 and 10 d of culture were pooled for assay.

†Assay performed on fluid collected after 14 d of culture.

‡All specificities known to be present on the immunising cell⁴ were represented.

§All known HLA-A and HLA-B specificities and most Aw and Bw specificities were represented.

was cytotoxic for any cell lacking both of these specificities; in particular, neither fluid recognised any of the other HLA specificities known to be present on the immunising cell⁴.

In order to test whether the A2 and A28 reactivities were separable by absorption, serial dilutions of fluids B9 and F4 were absorbed with constant numbers of each of three types of PBL: A2⁺ cells, A28⁺ cells and, as a control, A2⁻, A28⁻ cells. The residual cytotoxic activity against both A2⁺ and A28⁺ target cells was then measured (Table 2). For each fluid, absorption with a constant number of A2⁺ cells significantly reduced the cytotoxic activity against both A2⁺ and A28⁺ target cells. Similarly, absorption with A28⁺ cells significantly reduced the cytotoxic activity against both types of target cells. These results suggest that fluids B9 and F4 contain antibody which is directed against a cross-reactive determinant present on both A2⁺ and A28⁺ cells. Although the cross-reactivity between these cells is well established, its molecular basis is not yet fully understood⁹. Antibodies such as those described here should prove valuable tools in analysing these problems. Figure 1 shows that fluids B9 and F4 each showed some binding activity to the A2⁻ cell lines. Because both A2⁻ variants have been shown to lack surface A2 and A28 (refs 4 and 6, and D. P., unpublished results) we attribute this binding to the production of one or more additional antibodies by these fragments. Also, because no extra activities were seen in the extended typing panels, these antibodies may not recognise (or not be cytotoxic for) antigens found on normal human PBL. These points will be explored more fully in a later report (L. A. L. *et al.*, in preparation).

Many laboratories have produced xenogeneic anti-HLA antisera^{10,11}. Our approach differs from previous work in that murine anti-HLA antibodies were produced *in vitro*, and that, even though a whole cell was used as the immunogen, we obtained antibodies which, without further purification, were specific with respect to HLA. The value of *in vitro* cloning techniques for the production of homogeneous antibodies to cell

Table 2 Absorption of discriminator fluids

Absorbing cell	Cytotoxic titre remaining after absorption			
	Fluid B9*		Fluid F4†	
	Target cells A2 ⁺ , A28 ⁻ A2 ⁻ , A28 ⁺		Target cells A2 ⁺ , A28 ⁻ A2 ⁻ , A28 ⁺	
B.C. (A2 ⁻ , A28 ⁻)	32	≥ 64	4	2
K.W. (A2 ⁻ , A28 ⁻)	—	—‡	4	2
J.S. (A2 ⁺ , A28 ⁻)	4	4	0	0

One µl (45,000) absorbing cells were incubated with 1 µl culture fluid for 1 h at 37 °C, after which 1 µl (2,500) FDA-labelled target cells were added, and the cytotoxic test carried out as in Table 1.

*Day 14 collection. Pre-absorption titres: A2⁺, A2⁻ target, ≥ 64; A2⁻, A28⁺ target, ≥ 64.

†Day 7+10 collection. Pre-absorption titres: A2⁺, A2⁻ target, 4; A2⁻, A28⁺ target, not done.

‡Not done.

surface antigens is widely recognised^{1,2,12,13}. This report demonstrates the ability of the mouse to recognise a well-defined human cell-surface alloantigen, and describes conditions under which there is a reasonable probability of finding antibodies specific with respect to HLA. In addition, we have shown the value of using HLA⁻ variant cell lines⁸ for the rapid identification of these antibodies. The mouse spleen fragment culture system, as used here, provides a versatile way of obtaining antibodies to human cell surface antigens in quantities suitable for analytical work^{1-3,14}. This system also provides a way of enriching for antibody-forming cells of a desired specificity; these may then be expanded by techniques such as transformation or somatic cell hybridisation into a more permanent source of the desired antibody.

Coupling PPD to tumour cells enhances their antigenicity in BCG-primed mice

STUDIES of cell cooperation and of the carrier effect in the induction of antibody formation and in delayed hypersensitivity¹ can predict, and have indeed shown²⁻⁴, that combining an antigenic determinant which evokes a powerful T cell response with a weak antigen should greatly enhance the immunogenicity of the latter by providing 'antigenic help'.

Tuberculin (purified protein derivative, PPD) is a particularly effective carrier antigen. Long lasting and powerful T-cell reactivity (or delayed hypersensitivity) to tuberculin can readily be induced by infection with *Mycobacterium tuberculosis* vaccine (BCG). On the other hand, PPD itself does not induce delayed hypersensitivity but elicits reactions in the sensitised host. This property allows the effects of 'antigenic help' to be distinguished from changes in immunogenicity produced by chemical modification of the antigen simply by comparing the effects in BCG-primed and normal animals. Furthermore, there is little, if any, antibody response to PPD itself. Previous work from our laboratory has shown that PPD acts as a powerful carrier for the raising of anti-NIP antibodies in BCG-positive but not in BCG-negative hosts⁵. Immunising BCG-positive animals with PPD coupled to a weak protein antigen (for example, $\beta 2$ microglobulin) similarly enhances markedly the amount of anti- $\beta 2$ microglobulin that can be made (P. J. Lachmann, unpublished observations). We here report on the use of chemical modification with tuberculin for producing 'antigenic help' in raising immunity to the tumour specific transplantation antigens (TSTAs) of methylcholanthrene-induced sarcomas in syngeneic mice.

The tumours used were induced in female C57B1/10 ScSn (B10) mice by the subcutaneous implantation of 0.5 μ g 3-methylcholanthrene and were selected for immunogenicity as previously described⁶. The two tumours used in this study (designated MC 6A and MC 6B) were produced in a single mouse and were found to be non-crossreactive in a rejection assay. In initial experiments, tuberculin (PPD, Central Veterinary Laboratories, Weybridge, Surrey) was coupled directly to the irradiated tumour cells using redistilled glutaraldehyde at a final concentration of 0.005 M for

Fig. 1 Specificity of protection by cells coupled to Con A-PPD. Groups of three mice were immunised with either MC 6A (Δ) or MC 6B (\circ) cells coupled to PPD as in the legend to Table 1. Animals were challenged with 2×10^5 cells of either MC 6A (a) or MC 6B (b). Groups of unimmunised mice (\bullet) were similarly challenged. Mean tumour diameters were measured at 3-d intervals. Error bars represent \pm s.e.m.

2 h at room temperature. This procedure, however, seemed to cause damage to the tumour specific antigens and for this reason an alternative strategy was employed. The tuberculin was coupled to concanavalin A (Con A) using glutaraldehyde as above. For this purpose 10 mg of Con A (Calbiochem) in 1 ml was mixed with 10 mg of 125 I trace-labelled PPD also in 1 ml and redistilled glutaraldehyde was added to a final concentration of 0.006 M. After 2 h at room temperature the reaction was stopped by the addition of 1/10 volume of molar lysine. The mixture was then fractionated by affinity chromatography on G75 Sephadex. The material passing through this column (more than 95% of the tuberculin added) was rejected and then Con A and Con A-PPD were eluted from the column with 0.1 M α -methylglucose. The Con A concentration in the eluted peak was measured by the agglutination titre on guinea pig erythrocytes and the PPD by counting the 125 I. This isolated Con A-PPD was dialysed to remove sugar and added to irradiated ($10,000$ R) tumour cells (the equivalent of 20 μ g PPD was added to 10^8 cells). After incubation at room temperature for one hour, the cells were washed three times and the amount of bound 125 I determined by counting the washed cells in a γ counter; 25–50% of the added counts bound to the cells. The amount offered to the cells was chosen to give between 2 and 5×10^6 molecules of PPD per cell.

Groups of animals were immunised as described in Table 1. All the immunisations were performed on both BCG-primed and control (BCG-negative) animals to allow the role of delayed hypersensitivity to tuberculin to be assessed. Immunisation with tumour cells mixed with tuberculin was compared to immunisation with PPD-coupled cells. This allows the effect of injecting the cells into a site of delayed hypersensitivity reaction in the former case to be compared with 'antigenic help' in the latter. The effect of Con A coupling alone was also assessed.

From the results of the experiments as shown in Table 1 and Fig. 1 the following effects can be clearly seen: (1) powerful augmentation of immunity is seen in the test animals (group h) which are immunised so as to produce specific tuberculin help in immunisation (Table 1 and Fig. 1). It is of interest that the specificity of the rejection assays with regard to 6a and 6b is well maintained (Fig. 1); (2) the BCG status of the animal itself does not confer any

Table 1 Immunisation groups using Con A-PPD

Immunisation regime	Antigenic Ratio	
	Control (no BCG given)	BCG-primed
Irradiated cells only	a 1.7	b 1.5
Irradiated cells reacted with Con A	c 1.6	d 1.5
Irradiated cells mixed with PPD	e 1.4	f 1.0
Irradiated cells coupled to PPD	g 1.2	h 10.7

12–20-week-old C57B1/10 ScSn (B10) mice (OLAC, Bicester) were immunised with one tenth of the human intradermal dose of BCG (Glaxo, Greenford) in 0.2 ml saline by intraperitoneal injection. After two weeks, groups of three BCG-primed and untreated mice were injected with the following subcutaneously into the right groin in 0.2 ml saline: groups a and b: 10^7 irradiated 6A cells, groups c and d: 10^7 6A cells reacted with Con A, groups e and f: 10^7 6A cells mixed with PPD, groups g and h: 10^7 cells coupled to PPD through Con A as described. A week later, all groups received 10^7 irradiated cells subcutaneously into the right groin as a booster immunisation. Ten days after this the mice were challenged with 2×10^5 live 6A cells injected subcutaneously in 0.1 saline also into the right groin. A group of immunised mice was also challenged. Tumour diameters were measured with calipers in two perpendicular planes and the mean taken. Results are expressed as an antigenic ratio: mean tumour diameter in unimmunised mice/mean tumour diameter in immunised mice. An antigenic ratio (A.R.) of greater than 1.0 indicates some immunity. The antigenic ratios shown are based on measurements on the sixteenth day after challenge.

increased immunity to the tumours (Table 1). If anything, the BCG-positive animals support tumour growth slightly better than do BCG-negative animals when uncoupled cells are used. In view of the widespread use of repeated BCG treatment in the immunotherapy of human tumours, it is worth pointing out that such repeated administration of BCG particularly at the tumour site is aimed at activating the macrophages, not at inducing tuberculin sensitivity; (3) there is no benefit to be seen from immunising with irradiated tumour cells into the site of the tuberculin reaction (Table 1). This is a manoeuvre that has in the past been claimed to give adjuvanticity⁷, but in the present model, benefit is not apparent; (4) Con A itself, when coupled to cells, produces no enhanced response (Table 1).

The rejection assay is believed to represent predominantly a cell-mediated reaction and therefore is likely to represent cooperation between the two sets of T cells. This potentiation effect clearly requires the 'carrier' molecule (tuberculin) to be coupled to the tumour cell rather than mixed with it and given into a pre-sensitised host. The conditions are thus typical of the carrier-hapten situation found in T cell-B cell cooperation, the PPD being the carrier and the tumour specific antigen, the hapten.

The tumours studied were selected for immunogenicity. Immunisation with three or more injections of irradiated tumour cells on their own is capable of producing a good degree of immunity. Further studies are in progress to see to what extent resistance can be achieved to tumours of lower degrees of immunogenicity.

The technique here described is of wide applicability, since Con A reacts well with nearly all cells and particularly with tumour cells, and the single Con A-PPD reagent can therefore be used for coupling PPD to different cells at will. Furthermore, since BCG has been frequently given without ill effect to humans with tumours, there would seem to be no ethical problem in extending studies of this kind to immunotherapy of human tumours.

Host-donor cellular interactions in the treatment of experimental osteopetrosis

OSTEOPETROSIS is a rare bone disease of man, animals and birds¹. A striking feature is the failure of resorption of bone during growth and a reshaping of the skeleton so that the medullary cavities of shaft bones, normally containing only soft tissue—bone marrow—are filled with unabsorbed primary spongiosa causing a characteristic opaque radiological appearance that gives the disease its name. The osteoclast, a multinucleated giant cell, is considered to be responsible for the resorption of bone², and it has long been held that osteopetrosis is due to deficient osteoclasts. That the defect had a cellular rather than a humoral basis¹ was indicated when it was shown

that bony resorption in osteopetrotic mice was resumed after short periods in parabiosis with normal litter mates^{3,4} (which also showed that a circulating cell was involved) and after infusions of phenotypically normal and histocompatible haematopoietic cells^{5,6}. The subsequent and often rapid disappearance of the calcified material suggested to us that a new and proliferating population of cells was responsible, and to test this donor cells were tracked by a chromosome marker technique⁷. We now report that only low proportions of donor cells were located.

We used microphthalmic mice which suffer from osteopetrosis and were derived from Grüneberg⁸ (G) and bred at the MRC Radiobiology Unit, Harwell. The recessive *mi* gene in the homozygous state determines osteopetrosis. The *mi* gene was bred into the standard CBA/H inbred strain^{4,6} and thus in various combinations with the G strain indicated in Tables 1–3 it was possible to use the T6 chromosome marker because CBA/H and CBA T6T6 inbred strains are immunologically uniform. Because of closed colony conditions the G strain has greatly reduced heterozygosity⁴ also allowing intra-strain transplantation.

Fig. 1 Radiographs of osteopetrotic tibias ($\times 8$). Left, 28-d-old untreated G *mi* mouse. Note absence of medullary cavity. Centre, G *mi* mouse injected intraperitoneally at birth with haematopoietic cells. At 175 d partial resorption (\pm) had occurred but the metaphysis and submetaphyseal shaft were osteopetrotic. Right, G *mi* mouse injected intravenously at 19 d with haematopoietic cells and killed 29 d later. Resorption was subtotal (+), only the metaphysis was osteopetrotic.

In the three experiments reported here the donated hybrid cells (T6T6 \times G)_{F1} were unable to react immunologically against the host—except by virtue of the H-Y antigen to which the stocks are poor responders. On the other hand, in some instances the host could formally react against non-H-2 antigens of the donated cells.

Resorption in shaft bones was evaluated at the times shown in Tables 1–3, and estimated arbitrarily by radiology and histology as 'partial' (\pm) when resorption had clearly started but which was far from complete, and 'sub-total' (+) when it was approaching completion. In our hands, a patch of osteopetrosis usually persisted at the growth plate of long bones (Fig. 1). The cytogenetic status was also estimated at the times shown in Tables 1–3. The behaviour of vertebrae, ribs and membrane bones are not described here. Serious defects such as blindness and failure of eruption of teeth were unaffected.

The results of the three experiments were as follows: (1) Microphthalmic G mice injected intraperitoneally at birth with bone marrow from normal hybrid (T6T6 \times G)_{F1} mice showed subtotal or partial resolution of the osteopetrosis within 2 months. Only low proportions of T6-marked donor cells were detected in the spleen and bone marrow (Table 1). Persistence of donor cells, formally histoincompatible, may be attributed to immunological tolerance of the newborn to non-H-2 antigens. (2) In older mice injected intravenously, the resolution of the osteopetrosis was partial and in none were donated cells detected a month and more after treatment (Table 2).

Table 1 Chimaerism and results of treatment of newborn microphthalmic mice by intraperitoneal injection of allogeneic bone marrow suspension from phenotypically normal T6-marked mice

mi no.	Host stock	Host age and sex	Donor stock and sex	Cell dose ($\times 10^{-6}$)	% Dividing donor stock cells in host		Degree of resolution of osteopetrosis at time (d)
80	G	< 24 h ♀	(T6T6 \times G)F ₁ ♀	5	Spleen	1	+ at 55

83	G	1 d ♀	(T6T6 \times G)F ₁ ♀	7	Spleen	2	+ at 58
					Bone marrow	1	

Microphthalmic mice are difficult to maintain; as they are edentulous, they are weaned onto a wet mash. The T6-marked cells were detected by a standard cold spread method⁷ and 100–300 metaphase plates were scored in all preparations. The T6 marker detects dividing cells but does not reveal their identity.

Table 2 Results of treatment of weanling microphthalmic G mice by intravenous injection of allogeneic bone marrow suspension from phenotypically normal T6-marked mice

Mice were anaesthetised with avertin and parabiosed by the coelomic method. Braided silk (5/0) was used to suture the abdominal walls and the skin incision was closed with metal clips. At separation the normal anatomy was restored. Pairs were housed individually and received food pellets, wet mash and tap water *ad libitum*. To increase the number of metaphases for scoring, this group received sheep red blood corpuscles intraperitoneally 4 d before being killed. Previous experiments had shown that while the bone marrow was mitotically active the spleens were not. Separated leukocytes from the peripheral blood were cultured by Festenstein's method⁸.

(3) Four microphthalmic mice, after parabiosis to normal (T6T6×G)F₁ hybrids, showed partial resolution of osteopetrosis. Four months later, cells were detected in the haematopoietic tissues in the three syngeneic matchings, the greater proportion in the spleens and peripheral blood no doubt being due to antigenic stimulation (Table 3).

The results indicate that in a syngeneic combination (3) or when immunological tolerance of the newborn can be invoked in allogeneic matches (1), donated cells may persist in the microphthalmic recipient but in very small proportions. In the allogeneic match (2) no such cells were found 1 month later (compare the loss of grafts after 1 month in similar skin grafting experiments⁴). Nevertheless all groups showed resolution of the osteopetrosis to a greater or lesser degree in individuals.

It is possible that the weanlings in group (2) and the one successful case of parabiosis across an immunological barrier, where no donated cells were subsequently found, did have small and undetected populations of donor cells, which further experiments with mitotic stimulants may reveal. For the present, however, we postulate that allogeneic donor cells were eliminated but during their limited period of residence had caused considerable resorption of bone by providing osteoclastic precursors or had triggered the recipient's osteoclasts into effective function, comparable to the T-B cell-cell interactions of immunology. Experiments are in progress to investigate whether the resolution of osteopetrosis is permanent in these conditions, which would support the 'trigger' theory.

In experiment (1) and even in (3) where the spleen and separated leukocytes from the peripheral blood were under stimulation by foreign antigen, the donor population was in a minority and there was no 'take over', as would be presumed to have occurred in Walker's⁵ experiments where the recipients had been lethally irradiated before treatment.

We thank Mr M. J. Haddaway, Mr M. J. Corp and Mr P. Adams for radiology and Mr C. Williams for histology.

Cellular localisation of human urogastrone/epidermal growth factor

HUMAN urogastrone (hUG) is a polypeptide prepared from urine and is chemically similar to mouse epidermal growth factor (mEGF) prepared from submandibular salivary glands. Both these substances stimulate fibroblast proliferation in tissue culture systems. hUG and mEGF inhibit gastric acid secretion in experimental animals and hUG produces an identical effect in man. We show here, using immunofluorescent techniques,

that hUG is present in the duct cells of human submandibular gland and in Brunner's gland cells in the first part of the duodenum. This work suggests that these polypeptides may have a role in mucosal growth and control of gastrointestinal secretion.

The fact that peptic ulcer undergoes remission in pregnancy¹ led to the discovery of a powerful inhibitor of gastric acid secretion termed urogastrone in urine. This inhibitor has been shown to consist of a single polypeptide chain of 53 amino acids containing three disulphide bonds². Independently, Cohen and his colleagues³ have isolated a substance from mouse submaxillary glands known as epidermal growth factor (mEGF),

Fig. 1 Fluorescence can be seen as the light areas in *a*, the cells of the ducts of the submandibular glands and *b*, in the cells of the glands of Brunner in the first part of the duodenum.

which is closely related structurally to urogastrone and in biological activity it seems to be identical⁴. Both are powerful mitogens causing epithelial proliferation and keratinisation of squamous epithelial cells. They both inhibit gastric acid secretion and furthermore, they share common receptors in cultured human fibroblasts⁵. Preliminary physical data on a human epidermal growth factor (hEGF)⁶ suggests that the material in question is urogastrone².

Purified human urogastrone is an effective inhibitor of gastric acid secretion in normal male subjects⁷ and in patients with duodenal ulcer⁸ and Zollinger-Ellison syndrome, a disease due to an abnormally high circulating level of the hormone gastrin⁹. The cells of origin, storage or secretion of urogastrone, however, have not been identified in man. Urogastrone can be detected in human urine after a variety of surgical ablative procedures¹⁰, whereas (mEGF) has been found in specialised cells of the submandibular glands¹¹, and this finding prompted the present enquiry.

Antibodies to hUG were raised in rabbits¹². Specimens of the following normal human tissues were placed in polythene bags immediately after surgical excision, fixed in liquid nitrogen at -70 °C for 10 min, and were subsequently stored at -25 °C for further processing: submandibular salivary glands, parotid salivary glands, oesophagus, antrum and fundus of stomach, duodenum, jejunum, colon, breast, pancreas, ovary, adrenal, thyroid, kidney, bladder, liver, prostate, smooth muscle, skeletal muscle, cardiac muscle and thymus were studied. Frozen sections were cut and the slides exposed for 20 min to specific rabbit hUG antiserum without dilution and at 1 : 20 dilution using saline. The slides were washed for 20 min, and sheep anti-rabbit fluorescein-labelled immunoglobulin (Wellcome) was applied for a further 20 min followed by a final rinse. The

sections were then examined under ultraviolet light. Control sections from the same tissues were processed using nonspecific rabbit serum and also in a separate series using hUG absorbed specific rabbit antiserum. Adjacent sections of all tissues were stained with conventional haematoxylin and eosin to allow identification of cell types more easily in comparison with the fluorescein-labelled sections. An alternative method of fixation using buffered picric acid formaldehyde (pH 7.3) for 48 h before section cutting and application of the double layer fluorescence technique gave similar results to those obtained with the cryostat material. Fluorescence was seen in the cells of the ducts of human submandibular salivary glands and in the cells of Brunner's glands of the duodenum (Fig. 1a, b). Examination of sections from all the other tissues and of all control sections failed to reveal any appreciable fluorescence. An alternative freeze-drying and formaldehyde vapour fixation technique followed by immunostaining procedures has been reported¹⁸ to give an extremely clear picture of localisation of mEGF, but is much more time consuming than the methods outlined here for human tissues.

Our tests indicate that immunoreactive urogastrone/epidermal growth factor is present in specialised cells of the human submandibular salivary gland and also in the cells of the glands of Brunner in the duodenum. These findings may explain why in previous studies significant amounts of urogastrone could be detected in urine following different surgical ablation procedures in man¹⁰. No case examined so far has involved ablation of these two specific areas.

Our results also raise the question of the nature of the gastric acid inhibitory hormone 'enterogastrone', said to be liberated from the duodenum by fat ingestion in the studies of Kosaka and Lim¹⁴ (reviewed in detail by Gregory¹⁵). Could this 'enterogastrone' be urogastrone, a well-established potent inhibitor of gastric acid secretion and now localised in Brunner's glands? Furthermore, it is difficult to avoid speculation that the presence of a powerful growth factor at two sites in the gastrointestinal system is probably related to the known rapid turnover of the cells lining the gut¹⁶.

Renal actions of prostacyclin

A NEW and important member of the arachidonate-thromboxane-prostaglandin system, prostacyclin (PGI₂), has recently been isolated¹⁻³. This bicyclic prostaglandin has been shown to be synthesised from the prostaglandin endoperoxides PGG₂ and PGH₂, by arteries, veins, heart and other tissues in several species, including man¹⁻⁷. PGI₂ is a powerful inhibitor of platelet aggregation and relaxes arterial strips^{1,2,4,5}. It is 30 times more potent than PGE₁ as an inhibitor of platelet aggregation, and in the intact dog promotes a dramatic reduction in systemic blood pressure^{1,2,8,9}. It has also been suggested that PGI₂ is a potent coronary vasodilator and anti-atherogenic compound¹⁰⁻¹², and that it plays an essential part in the homeostasis of the cardiovascular system^{1,2,4,5,11,12}. The kidneys receive a large portion of the cardiac output and have an extensive vascular tree, and so PGI₂ may be extremely significant in regulating kidney function. Human and rabbit renal cortical microsomes have been found to convert PGG₂ to PGI₂ (ref. 13), but nothing is known of the renal effects of PGI₂. Therefore, this study was designed to evaluate the effects and significance of an intrarenal infusion of PGI₂ on renal haemodynamics, urinary function and renal vein plasma renin activity, and to compare these effects with those produced by PGE₂ and PGD₂, two prostaglandins known to be synthesised by the kidney and to affect renal function.

Table 1 shows the effects of intrarenal infusions of PGI₂, PGD₂ and PGE₂. All three prostaglandins markedly elevated renal blood flow. The increases in blood flow produced by PGI₂ and PGD₂ were due to an enhanced blood flow to both the outer and inner cortical regions as shown in Table 1. The increases in blood flow to the inner cortex were greater than those in blood flow to the outer cortex, thus shifting the intrarenal distribution of blood flow to the inner cortex. Although no values for the PGE₂ experiments are shown, radionuclide-labelled microspheres were used in one experiment, and results similar to those seen with PGI₂ and PGD₂ were obtained.

All three prostaglandins produced similar increases in renal blood flow without a change in glomerular filtration rate. Their effects on urinary function, however, were dissimilar (Table 1), both PGI₂ and PGE₂ promoting a natriuresis and diuresis, and PGD₂ having no significant effect on the urinary flow rate and the fractional excretion of sodium. In addition, PGI₂ and PGE₂ but not PGD₂, significantly elevated the excretion rate of potassium (not shown). At no time during the infusion of these prostaglandins were changes noted in systemic blood pressure, heart rate or contralateral renal function, indicating that at the dosage employed, the effects induced by these prostaglandins were restricted to the infused kidney. In two experiments, the PGI₂ solvent and the PGI₂ metabolite, 6-keto-PGF_{1α}, were infused separately and found to have no significant effect on renal blood flow, urinary output or renal vein plasma renin activity. This implies that neither the solvent nor the metabolite were responsible for the renal effects induced by PGI₂.

In a previous report, we demonstrated that the infusions of PGD₂ and PGE₂ at a 10-fold higher rate of 0.4 µg per kg of body weight per min produced changes in renal function qualitatively similar to the effects elicited by PGD₂ and PGE₂ in this study¹⁴. No systemic effects were noted. PGI₂ at this higher rate of infusion (0.4 µg per kg per min) decreased systemic blood pressure and increased heart rate. This indicates that PGI₂ leaving the kidney was not effectively metabolised by the lungs, and is consistent with the observation made earlier by Waldman *et al.*¹⁵ that the vasodepressor response of PGI₂ in the dog is not diminished by passage through the lungs, in contrast to a dramatic reduction in the vasodepressor effect of PGE₂. This phenomenon might be explained in one of three ways. First, PGI₂ undergoes little metabolism in the lung;

second, PGI₂ undergoes some metabolism in the lung, but because of its marked potency, enough escapes to cause systemic effects; third, the amount of PGI₂ reaching the lung during the higher infusion rate exceeded the capacity of the lung to metabolise it. These observations suggest that if PGI₂ is formed and released by the kidney in sufficient quantity, it might function as a circulating vasodepressor substance.

The pattern of blood flow changes induced by the three prostaglandins is similar to that produced by the prostaglandin precursor, arachidonic acid, and other renal vasodilators^{16,17}. Their similar haemodynamic effects, but differing effects on urinary function suggest that PGI₂ and PGE₂, but not PGD₂, either directly and/or indirectly inhibit sodium and water reabsorption. Although the present experiments do not elucidate the mechanism by which PGI₂ promotes a natriuresis and diuresis, PGE₂ has been shown to inhibit directly the reabsorption of sodium in the nephron^{18,19}.

Of the three prostaglandins, only PGD₂ significantly elevated renal vein plasma renin activity when infused at a rate of 0.04 µg per kg per min. Vander²⁰ also observed that PGE₂ infusion in a similar dose did not alter renin release. In a previous series of experiments, however, we found that when PGE₂ was infused at a 10-fold higher rate (0.4 µg per kg per min) renal vein plasma renin activity was increased¹⁴; Yun *et al.*²¹ also found this. A comparison of the haemodynamic and urinary effects of PGE₂ at the two doses (0.04 and 0.4 µg per kg per min) used in our studies revealed that the higher dose produced an increase in renal blood flow which was twice as great as that produced by the lower dose, while the diuretic and natriuretic effects were not appreciably different at the two dose levels. Previous demonstrations of increased renin production following administration of arachidonic acid or PGE₁ led to the suggestion that prostaglandins may act directly on the juxtaglomerular cells to release renin. This conclusion

has been questioned, as it was pointed out that the accompanying natriuresis *per se* may have triggered renin release by presenting more sodium to the macula densa²². The present observation might be explained by precisely the opposite argument, that the renal haemodynamic effects induced by PGI₂ and PGE₂ are promoting renin release whereas the natriuresis is inhibiting release. Our additional experiments have used a non-filtering kidney model in which the delivery of sodium to the macula densa is prevented; the infusion of either PGI₂ or PGE₂ at the lower dose (0.04 µg per kg per min) then increased renin release. In the intact kidney, either an elevated sodium load at the macula densa as suggested by Vander²³, or an action of PGE₂ and PGI₂ to reduce ion flux across the macula densa as postulated by Thureau *et al.*²⁴ may have blunted an increase of renin release. The stimulation of renin release induced by PGD₂ is unopposed because of the absence of a natriuresis.

Our evaluation of PGI₂ indicates that when infused intrarenally it produces changes in renal haemodynamics and urinary function which are qualitatively identical to those produced by PGE₂. It is impossible at present to state which prostaglandin (PGI₂, PGE₂ or PGD₂) is the major renal prostaglandin mediating the effects of endogenous arachidonate released following neural and hormonal stimulation. This will be resolved by the future development of analytical techniques which will permit measurement of the levels of renal prostaglandins in physiological conditions. However, it is noteworthy that PGI₂ escapes metabolism by the lung; if the kidney is a major source of PGI₂ it may have significant effects beyond that organ. Conversely, if arterial levels of PGI₂ are sufficiently high, production of PGI₂ elsewhere in the body may have significant effects on renal function. It should be noted, however, that PGI₂ did not exhibit any superior potency to PGE₂ in its effects on renal function. Finally, we obtained

Table 1 The effects of intrarenal infusions of PGI₂, PGD₂ and PGE₂

Infusion periods	RBF (ml per min per g of kidney)	OCBF (ml per min per g of tissue)	ICBF (ml per min per g of tissue)	RF	V̇ (µl per min per g of kidney)	FE _{Na} ⁺ (%)	RVPRA ng per ml per h
	N = 9	N = 8	N = 8	N = 8	N = 9	N = 9	N = 5
Control	4.1 ± 0.6	8.0 ± 1.2	4.4 ± 0.6	1.9 ± 0.1	7 ± 1	0.94 ± 0.25	5.6 ± 1.5

Values (right renal) are expressed as the mean ± s.e.m.; N, no. of animals; *, *P* < 0.05 as determined by the paired *t* test. RBF, renal blood flow; OCBF, outer cortical blood flow; ICBF, inner cortical blood flow; RF, ratio of cortical blood flows (outer cortical to inner cortical blood flows); V̇, urinary flow rate; FE_{Na}⁺, fractional excretion of sodium; RVPRA, renal vein plasma renin activity. OCBF, ICBF, RF and RVPRA were not determined in all experiments because of technical difficulties. OCBF, ICBF and RF mean values are not shown for PGE₂ experiments, because intrarenal blood flow was not determined. Mongrel dogs of either sex (N = 22) were fasted 18 h before the experiment and allowed free access to tap water. The animals were anaesthetised with intravenous pentobarbital (30 mg per kg of body weight) and placed on a positive pressure respirator (Harvard Apparatus). Indwelling polyethylene catheters were inserted into the following vessels; the right femoral artery for monitoring of systemic blood pressure and collection of blood samples, the left femoral artery for advancement into the left ventricle, the left femoral vein for advancement into the right renal vein and the right femoral vein for the infusion of inulin to measure the glomerular filtration rate. A suprapubic midline abdominal incision was made and both ureters were cannulated. A right retroperitoneal flank incision was performed, and a hydraulic cuff (*In Vivo* Metric Systems) and electromagnetic flowprobe (Biotronix Laboratories) were placed on the renal artery. A 25-gauge infusion needle was inserted into the artery proximal to the flowprobe and hydraulic cuff, and normal saline was infused at 0.5 ml min⁻¹. One hour was allowed for stabilisation of renal function. Each experiment comprised two 15-min infusion periods (control saline infusion followed by PGI₂, PGD₂ or PGE₂ (0.04 µg kg⁻¹ min⁻¹) infusion), with three 5-min urine collections in each period. After the start of the second urine collection, arterial samples for inulin, sodium and potassium and renal vein samples for renin were collected. Midway through each period radionuclide-labelled microspheres (15 ± 5 µm ⁸⁵Sr, ¹⁴¹Ce and ⁵¹Cr, New England Nuclear) were introduced into the left ventricle with the exception of the PGE₂ experiments. PGD₂ and PGE₂ were dissolved in ethanol and stored at -20 °C until the day of the experiment, when the ethanol was evaporated off and the prostaglandins were dissolved in normal saline. PGI₂ was chemically synthesised according to the method of Corey *et al.*²⁵. It was dissolved in water and stored at -70 °C until several hours before the experiment; an aliquot of the stock solution was then dissolved in a Tris buffer at pH 9. At the end of this prostaglandin infusion period, the animals were killed and the kidneys removed, weighed and sectioned according to the method of Slotkoff *et al.*²⁶ for counting of radioactivity. Renin levels were measured by radioimmunoassay.

data which suggests that the net effect of either PGI_2 or PGE_2 on renin release is the summation of its stimulatory action by means of haemodynamic changes and/or a direct stimulation of the juxtaglomerular apparatus, versus a dampening effect produced by altered sodium transport at the macula densa.

Temperature-induced phase shift of daily rhythm of serum prolactin in gulf killifish

DAILY variations in circulating levels of the pituitary hormone prolactin have been reported in several vertebrates, including fishes¹⁻⁴. In some animals, the 24-h rhythm changes seasonally with respect to the time of day that maximum and minimum prolactin levels occur^{4,5}. It has been hypothesised that this seasonal change in phase of prolactin rhythm is an important component of the mechanism controlling seasonality in vertebrates⁶. Because water temperature is generally considered the principal environmental regulator of seasonal changes in reproduction and metabolism in many fishes, including the gulf killifish *Fundulus grandis*⁷, we determined the daily rhythm of serum prolactin concentrations in fish held at temperatures that are stimulatory (20 °C) or inhibitory (28 °C) for reproductive development. We found that an increase in water temperature from 20° to 28 °C phase shifts the daily variation of serum prolactin with respect to the daily photoperiod in *F. grandis*.

There were variations in serum prolactin concentration in gulf killifish maintained at water temperatures of either 20° or 28 °C ($P < 0.01$; $P < 0.05$, one-way analysis of variance). However, the phase relationships of the peaks and troughs of the two rhythms differed with respect to the daily photoperiod 12 h light and 12 h dark (12L:12D). Thus, the peak

level of prolactin in fish acclimated to 20 °C occurred at 1400 h (8 h after the onset of light) whereas the prolactin peak in fish acclimated to 28 °C occurred at 0600 h (onset of light) (Fig. 1). There was a highly significant interaction between the temperature of acclimation and the time of day of sampling ($P < 0.01$,

Fig. 1 Serum prolactin levels of gulf killifish acclimated to either 20 °C (●) or 28 °C (■). Both groups of fish were kept in a 12L:12D photoperiod regime—with light onset at 0600 h. The upper graph depicts the two unadjusted rhythms; sample size is adjacent to the mean prolactin levels, vertical bars represent standard error of the mean. In the lower graph the points depicting the prolactin rhythm of the 28 °C acclimated fish have been adjusted by 8 h to demonstrate the similarity in form of the two rhythms. Actual sampling times of the 28 °C acclimated fish are shown in parentheses. Fish of both sexes were collected from Grand Isle, Louisiana in February and maintained indoors in 70-l aquaria which received filtered and aerated water (salinity 3‰) and approximately 2 g of flake food (TetraMin) once daily. Routine maintenance and feeding were done at random times during the day. After a 2-week preliminary acclimation at 20 °C and 12L:12D (approximately the March photoperiod regime of Grand Isle) fish were divided into two groups which received either 20° or 28 °C, 12L:12D and 3‰ salinity were maintained for both groups. After an additional 2 weeks of acclimation, the fish were killed at one of six different times of day. Blood was taken by heart puncture, allowed to clot under refrigeration and centrifuged. The serum was assayed with a double antibody technique utilising an antiserum to pollock prolactin and iodinated ovine prolactin¹². Because killifish prolactin was not available, we were unable to determine absolute levels of prolactin. However, a pooled reference standard was run which allowed us to ascertain relative differences in circulating titres of prolactin. Mean levels of prolactin were not significantly different between the sexes.

two-way analysis of variance). This interaction is due to differences in the phase relationship of the two rhythms. The significant interaction can be eliminated by shifting the rhythm of the fish acclimated to 28 °C to 8 h later in the day (Fig. 1). The mean serum prolactin concentrations (mean of all values throughout the day) did not differ between the two groups.

Our work reconfirms the often cited warning to researchers of the problems inherent in sampling at one time of day with the added caution that environmental factors other than photoperiod (for example, temperature) may influence hormone rhythms considerably. Further, the phase shift in the prolactin rhythm we induced by a temperature change may have important implications in the understanding of the seasonal physiology of the gulf killifish. Increased water temperature causes gonadal regression in several species of fish⁸ including *F. grandis*. Gulf killifish collected from their natural environment have ripe gonads when ambient temperatures are 20 °C (early March) and regressing gonads when ambient temperatures reach 28 °C (May–June) and higher (July–August)^{7,9,10}. In our experiment male killifish acclimated to 28 °C had a significantly lower gonadosomatic index ((gonad weight/body weight) × 100) than those acclimated to 20 °C ($P < 0.05$ Student's *t* test). Apparently, the effects of temperature on the gonads may be mediated by altering the phase of the prolactin rhythm. In male killifish maintained on a 15L:9D regimen, daily injections of prolactin 8 h after the onset of light (the time of peak prolactin levels in the fish acclimated to 20 °C) stimulated the reproductive system whereas prolactin injections at other times of day including light onset (the time of peak prolactin in fish acclimated to 28 °C) were ineffective⁷.

The annual cycle of reproduction in teleost fishes is regulated by changes in daylength, temperature or a combination of both⁸. The strategy used seems to depend more on ecological demands than on phylogenetic relatedness. As in birds and mammals⁸, circadian mechanisms control reproduction in a photosensitive teleost¹¹. Our results indicate that temperature control of reproduction in an ectothermic thermosensitive species may also be mediated in part by circadian systems.

Cyclic AMP and noradrenaline sensitivity fluctuations in regenerating newt tissue

Limb regeneration in the adult newt is dependent on the nervous system^{1,2} but the biochemical events involved are not well understood. A role for catecholamines (CA) seems likely since histofluorescence has shown that CA are more abundant in regenerates than in other newt limb tissues³. It has also been shown that reserpine, which promotes the release of CA from nerve terminals, accelerates regeneration⁴, whereas chlorpromazine⁵, guanethidine⁵ (both CA release blockers) and α -methyl-*p*-tyrosine⁶ (CA biosynthesis inhibitor) inhibit it. Studies suggest that in many biological systems the CA effects are linked to the activation of membrane adenylate cyclase with subsequent production of cyclic AMP⁷. It has also been suggested that nerves may transmit trophic information by the stimulation of this enzyme^{8–11}. To test this hypothesis further, regenerates were isolated either for direct measurements of cyclic AMP or for stimulation with CA *in vitro*¹². This method avoids the possible nonspecific effects due to systemic administration of CA. We now report that the fluctuations of cyclic AMP found at the various stages of regeneration correlate with noradrenaline (NA) sensitivity changes.

Adult newts *Triturus cristatus* were housed and handled and their limbs amputated as before⁶. Characterisation of the stages was performed on a morphological basis¹³, which is the most reliable criterion for specimen selection¹⁴. In order to measure true endogenous levels of cyclic AMP, isolated regenerates were collected in 0.25 ml of batracian Ringer¹⁵ and immediately heated in a boiling water bath for 10 min. A pool of 3–10 regenerates, depending upon the amount of regenerating tissue, was routinely used. The cyclic AMP accumulation induced by noradrenaline (or

Fig. 1 Endogenous cyclic AMP levels (pmol per mg protein) in newt forelimb regenerates at various stages of development. The various stages were designed as described elsewhere¹³. Amp = amputation, WH = wound healing, EDD = early dedifferentiation, LDD = late dedifferentiation, MEB = moderate early bud, EB = early bud, MB = medium bud, LB₁ = early LB, LB₂ = late bud, LB₂ = late LB, PAL = palette, ED = early digits, MD = medium digits, LD = late digits. Regenerating tissue was removed with iridectomy scissors from live animals placed under binocular magnifying glass. After removal, the tissue was immediately plunged into a glass homogeniser (containing 0.25 ml of Ringer solution) kept in boiling water. The heat inactivation was continued for 10 min. A pool of 10 (WH) to 3 (LD) regenerates was used for 1 homogenisation, the total number of experimental tubes at various stages being given in parentheses (= *N*). The tissues were then homogenised, at 4 °C, and centrifugation (4,000 r.p.m.) was performed at the same temperature. The pellets were used for protein determination²². Duplicate samples (50 μ l) of the supernatant were taken for the measurement of cyclic AMP using a saturation assay method²³. Values are mean \pm s.e.m. Statistical analysis was performed using Student *t* test for unpaired data. *, Significantly different from previous ($P < 0.01$) and next ($P < 0.001$) stages. †, Significantly different from LDD ($P < 0.05$). ‡, Significantly different from MB and Pal Stages ($P < 0.05$).

Fig. 2 Cyclic AMP increase (pmol per mg protein) induced by 10^{-4} M noradrenaline in newt forelimb regenerates at various stages of development. Pools of isolated regenerates were pre-incubated for 20 min at 35°C in 0.25 ml of Ringer solution¹⁵. After addition of theophylline (final concentration 5×10^{-3} M), which prevents the hydrolysis of cyclic AMP by phosphodiesterase, an incubation was carried out at 35°C for 10 min (total volume 0.33 ml) with noradrenaline. Controls were incubated in the absence of noradrenaline. The tissues were then inactivated by heat (see Fig. 1 for other experimental details). The increase in cyclic AMP above control is expressed as Δ . Values are mean (Δ) + s.e.m. (vertical bars) for the number of samples shown in parentheses (= N). In the absence of noradrenaline, the cyclic AMP values (pmol per mg protein) were 1.9 (WH 24 h), 6.8 (WH 48 h), 1.9 (WH 4 d), 3.4 (WH-EDD), 2.6 (LDD), 3.7 (late LDD), 2.7 (MEB), 3.3 (EB), 3.7 (MB), 4.0 (LB), 3.2 (LB₂), 4.2 (Pal), 4.4 (ED), 4.0 (MD) and 3.6 (LD). The abbreviations of the various stages are given in Fig. 1.

other adrenergic agonists) was measured as before¹². Some experiments were performed in the presence of an α - or β -adrenergic antagonist. Figure 1 shows that endogenous cyclic AMP levels fluctuate as a function of the stage of regeneration. Three distinct peaks of cyclic AMP were found and these occurred at the wound-healing (WH), at the moderate early bud (MEB) and at the late bud (LB) stages. The lowest values of cyclic AMP were found at the late dedifferentiation stage (LDD). Three peaks of cyclic AMP accumulation were also observed when isolated regenerates were exposed to 10^{-4} M NA (Fig. 2). In some experiments, pieces of tissue located under the wound were also exposed to NA and the results compared to those obtained with regenerates of the same forelimbs (Fig. 3). Regenerating tissues reacted to NA by a large increase in cyclic AMP concentration, while stump tissues did not. This implies that NA sensitivity differences may

exist between growing and resting limb tissues. Strikingly, the peaks resulting from NA stimulation (Fig. 2) roughly correspond to the peaks of endogenous cyclic AMP levels (Fig. 1). Incubation of regenerates at the WH and MEB stages was also performed in the presence of isoproterenol (ISO) or dopamine (DA). The former catecholamine stimulated cyclic AMP accumulation, while DA had no effect (data not shown). Moreover, in the presence of the β -adrenergic receptor antagonist, propranolol, or phentolamine, only the former was able to inhibit the cyclic AMP increases induced by NA (Table 1) or ISO (not shown). These results suggest that trophic information mediated by CA involves β -adrenergic receptors.

Thus, during the process of regeneration, fluctuation occurs in endogenous cyclic AMP levels and sensitivity of the tissue receptors to NA. It is tempting to correlate nerve activity, cell sensitivity to NA, endogenous cyclic AMP and the passage of one stage of regeneration to another. The first peak of cyclic AMP could be associated with the wound healing process (possibly linked to cell movements¹⁶) and the drop noted at LDD could be necessary for the occurrence of cell dedifferentiation. The following peaks might then be related to bursts of proliferation¹⁷, possibly linked to one or several phases of the cell cycle and to differentiation^{18,19}. Very recently, it was found that cyclic GMP levels also change during newt limb regeneration²⁰

Fig. 3 The effects of 10^{-4} M noradrenaline on the cyclic AMP concentration (pmol per mg protein) in regenerating or non-regenerating tissues of the newt. Regenerates at the LDD stage were removed (see Fig. 1), as well as skin of nonregenerating tissues dissected from the region distant from the wound A, or adjacent to it B. Empty bars are controls, filled bars represent noradrenaline-treated tissues. The experimental details were given in Fig. 2. Values are mean + s.e.m.

and the low values of cyclic AMP observed at LDD (Fig. 1) seem to coincide with high levels of cyclic GMP at the same stage²⁰. Fluctuations of both cyclic nucleotides in a related but opposite way may then be needed during the process of regeneration, at least at dedifferentiation stages, and it is possible that the cyclic GMP effects are mediated by another nerve trophic factor of peptide nature²¹. Such speculations are currently under investigation using newt forelimb regenerates.

Increases in cyclic GMP levels may not mediate relaxant effects of sodium nitroprusside, verapamil and hydralazine in rat vas deferens

It has been suggested that increases in cyclic GMP levels may be responsible for the promotion of contractions in a variety of smooth muscles¹⁻⁶. This suggestion was based on observations that agents known to be capable of contracting smooth muscles produced marked increases in cyclic GMP levels in the respective muscles¹⁻⁸. However, recent reports have concluded that, although increases in cyclic GMP levels do occur during contractions in some types of smooth muscle, the increases in cyclic GMP levels are not responsible for the initiation or promotion of the contractions⁹⁻¹². Part of the evidence for this conclusion was the observation that marked increases in cyclic GMP levels occurred during relaxation of smooth muscles by drugs such as nitroglycerol^{10,12}. Schultz *et al.*¹³ have shown that other smooth muscle relaxants including sodium nitroprusside, hydralazine, and D-600 (a methoxy derivative of verapamil) are all capable of increasing cyclic GMP levels in isolated segments of rat vas deferens. These authors also noted that the 8-bromo derivative of cyclic GMP was itself capable of relaxing the rat vas deferens in certain conditions¹³. It was concluded that, not only was cyclic GMP not a mediator of smooth muscle contraction, but it might in fact be responsible for the smooth muscle relaxant effects of the above drugs. We describe here studies performed in rat vas deferens. Our results are not consistent with the hypothesis that increases in cyclic GMP levels are responsible for drug-induced smooth muscle relaxation.

Schultz *et al.*⁸ have suggested that the increases in cyclic GMP levels which accompany smooth muscle contractions might be part of a negative feedback mechanism tending to reduce calcium influx or to increase calcium efflux, thus limiting or terminating the contractions. The suggestion that cyclic GMP may mediate the relaxant effects of some drugs is a logical extension of this hypothesis as, if the hypothesis is true, any drug which directly increases cyclic GMP levels in a smooth muscle should tend to lower intracellular ionised calcium levels and relax the muscle. However, in the experiments of Schultz *et al.*¹³ the effects of the relaxant drugs on cyclic GMP levels in the vas deferens were measured in the absence of extracellular calcium, and the effects of the drugs on muscle tension were not monitored. In our opinion, if direct correlations between cyclic nucleotide levels and drug-induced relaxation are to be made, it is essential that both parameters be measured. Therefore, the experiments described here were carried out in physiological salt solutions containing calcium, and the effects of relaxant drugs on both tension and cyclic nucleotide levels were monitored simultaneously in the same muscle segments.

In order to demonstrate the relaxant effects of drugs on the isolated vas deferens it was first necessary to contract the muscles. This was accomplished either by adding 30 μ M phenylephrine to the muscle baths or by exposing the muscles to 124 mM KCl¹⁰. The effects of these agents on tension developed by the muscles are shown in Fig. 1 together with the effects of verapamil and sodium nitroprusside on KCl- and phenylephrine-induced contractions. Verapamil at 20 μ M was capable of relaxing segments of rat vas deferens which had been previously contracted by KCl (Fig. 1 *a*) or by phenylephrine (data not shown). Pretreatment with 50 μ M verapamil for 30 s almost completely blocked the stimulatory effects of a subsequent dose of phenylephrine (Fig. 1 *b*). Similar results were obtained with hydralazine (not shown) although the onset of relaxation was slower than with verapamil and higher concentrations of hydralazine (1 mM) had to be used to obtain comparable degrees of relaxation. Sodium nitroprusside had no effect on contractions induced by phenylephrine (Fig. 1 *c*) or KCl (Table 1).

Cyclic nucleotide levels were determined in paired segments of rat vas deferens exposed to several combinations of stimulant and relaxant drugs. In agreement with previous reports⁸ cyclic GMP levels were markedly increased in segments of vas deferens exposed to KCl alone. For example, cyclic GMP levels were increased from 5.1 ± 1.6 pmol per g tissue in relaxed controls, to 31.9 ± 4.0 pmol per g tissue 5 min after KCl-induced depolarisation ($N=5$). The KCl-depolarised muscles could be relaxed by concentrations of hydralazine or verapamil which had no further effect on cyclic GMP levels (Table 1). These concentrations of hydralazine and verapamil were sufficient to completely relax the muscles within 6-10 min, although at 1 min after drug administration they were relaxed by only 16% and 38% respectively. Conversely, sodium nitroprusside failed to relax KCl-induced contractions of rat

Fig. 1 Representative tracings illustrating the effects of verapamil and sodium nitroprusside (SNP) on KCl- and phenylephrine-induced contractions of isolated rat vas deferens.

Table 1 Effects of hydralazine, verapamil and sodium nitroprusside on tension and cyclic nucleotide levels in rat vas deferens

Treatment	N	Cyclic GMP (pmol per g tissue)	Cyclic AMP (pmol per g tissue)	Relaxation (%)
KCl, 5 min (control)	5	33.0±1.5	683±74	—
KCl, 5 min+hydralazine last 1 min	5	33.6±2.6	658±31	16.4±1.5*
KCl, 5 min (control)	7	31.7±3.8	863±88	—
KCl, 5 min+verapamil, last 1 min	7	33.1±5.8	855±70	37.6±3.8*
KCl, 5 min (control)	6	30.2±6.5	621±138	—
KCl, 5 min+Na nitroprusside, last 1 min	6	67.8±13.8*	646±120	0.0
Phenylephrine, 2 min (control)	6	16.3±3.9	717±90	—
Phenylephrine, 2min+Na nitroprusside, last 1 min	6	120.5±19.6*	783±89	0.0

Paired segments of rat vas deferens were equilibrated in physiological salt solution as previously described¹¹. Both muscles of a given pair were then exposed to either 124 mM KCl or 30 µM phenylephrine for 5 or 2 min respectively. One muscle from each pair was also exposed to a relaxant drug for the last minute of the experiment. Concentrations of the relaxant drugs used were: verapamil, 20 µM; hydralazine, 1 mM; sodium nitroprusside, 0.5 mM in the phenylephrine experiments and 0.1 mM in the KCl experiments. Muscles were clamp-frozen at the appropriate times and cyclic nucleotides were extracted and assayed using standard techniques¹¹. Values represent means ± s.e.m. for the number of experiments indicated (N).

*Significantly different from corresponding controls ($P < 0.001$).

vas deferens, while significantly increasing cyclic GMP levels in these preparations (Table 1). Furthermore, 0.5 mM sodium nitroprusside, which had no effect on phenylephrine-induced contractions, increased cyclic GMP levels almost eightfold over the corresponding phenylephrine controls (Table 1). No significant changes in cyclic AMP levels were seen in any of the experiments. Thus, in the case of hydralazine and verapamil we were able to markedly relax the vas deferens without changing cyclic GMP levels, and in the case of sodium nitroprusside we were able to markedly increase cyclic GMP levels without relaxing the muscles. These results are not consistent with the suggestion that the relaxant effects of these drugs are mediated by increases in tissue levels of cyclic GMP.

It might be argued that the sodium nitroprusside-induced increases in cyclic GMP levels were activating mechanisms that tend to lower intracellular calcium, but that this effect was not sufficient to antagonise the contractile effects of phenylephrine or KCl. It should be noted, however, that both types of contractions could be relaxed by verapamil or hydralazine. The concentration of phenylephrine used in our experiments was submaximal, and phenylephrine-induced contractions could be almost completely blocked by pretreatment of the muscles for 30 s with relatively low concentrations of verapamil (Fig. 1). Cyclic GMP levels were not significantly altered by the verapamil pretreatment. Levels of the cyclic nucleotide were 15.8 ± 2.6 pmol per g tissue in the muscles exposed to phenylephrine alone and 11.3 ± 1.8 pmol per g tissue in muscles exposed to both verapamil and phenylephrine ($N=6$). Conversely, increases in cyclic GMP levels even larger than those shown in Table 1 were seen when the muscle segments were pretreated with sodium nitroprusside for 30 s before adding the phenylephrine. In these conditions cyclic GMP levels in the muscles exposed to both sodium nitroprusside and phenylephrine were increased more than 15-fold over the phenylephrine controls (from 15 ± 5 to 226 ± 27 pmol per g tissue, $N=3$). In spite of this large increase in cyclic GMP levels no detectable change in the phenylephrine-induced contractions was seen (Fig. 1). If cyclic GMP is in fact a mediator of relaxation, such a large increase in tissue levels of cyclic GMP should have at

least partially reduced the contractions caused by these submaximal concentrations of phenylephrine.

Our results indicate that increases in cyclic GMP levels are probably not responsible for the relaxant effects of sodium nitroprusside, hydralazine or verapamil in rat vas deferens. Further work is needed to clarify the role of cyclic GMP in smooth muscle relaxation.

Arginine-specific reagents remove sodium channel inactivation

PROTEINS are often suggested to be the molecular components of excitable membranes which confer voltage-dependent permeability properties on nerve and muscle cells. Because of the relatively low concentration of the protein molecules directly responsible for ionic conductances compared with other membrane components, the isolation, characterisation, and reconstitution of these proteins is still at a rather early stage. Certain aspects of the molecular nature of the conductance mechanisms of excitable tissues, however, can be deduced using chemical reagents which specifically modify protein molecules. In particular, the sodium inactivation process can be eliminated by treatment with various proteolytic enzymes^{1–3,6}. Of these, trypsin is probably the most selective, cleaving mainly at arginyl or lysyl residues⁴. Several investigators have suggested that just such an exposed positively charged residue might be responsible for blocking the sodium conductance pathway to produce inactivation^{5,6}. Therefore, it should be possible to alter or remove inactivation by changing the configuration and/or charge of the blocking residue with a reagent specific for the residue involved. Glyoxal, phenylglyoxal and condensed 2,3-butanedione are three such reagents which are very reactive with the guanidino group of arginine^{7–9}. This paper describes the effect on sodium inactivation of these agents when they are internally perfused in the squid axon.

Two methods of internal perfusion were used: the 'roller' method¹⁰, and the 'cannula' method¹¹. In either case, axons were then mounted in a plexiglass chamber designed for voltage clamping using conventional techniques^{12,13}. Feedback compensation was used in all experiments to reduce errors due to membrane series resistance.

Glyoxal was allowed to react with the inner surface of the axonal membrane by perfusing the fibre for 10–15 min with a 5 mM solution of the trimeric dihydrate in an internal solution at pH 9.0. The pH 9.0 internal solution by

itself produced only a slight reduction in peak inward sodium current, with little (if any) effect on inactivation as estimated from the steady-state inward current at the end of a 10-ms pulse. At the end of the reaction period, the glyoxal had reduced the peak inward current to approximately 50% of its original control value, but the steady-state current at the end of the 10-ms pulse had increased by 200%. This result seems to reflect the complete removal of inactivation in affected sodium channels, as the time constant of decay in the component of current that still inactivated was unaffected by glyoxal treatment. Figure 1 shows the effect of glyoxal treatment.

To quantify this effect, a 25–50-ms conditioning prepulse was used to determine the relationship between inactivation and membrane potential before and after glyoxal treatment. In Fig. 2b, the normalised peak inward current is plotted against conditioning potential. In the control case, the peak inward current is rapidly reduced as the conditioning prepulse becomes more depolarised until, for large prepulses, more than 90% of the peak inward current is inactivated. After treatment with glyoxal, a portion of the peak sodium current was inactivated with a voltage dependence similar to the control, but a large fraction of the current is unaffected by the conditioning prepulse even at large depolarisations. We associate this fraction with the sodium inactivation molecules that have reacted with glyoxal.

Fig. 1 Current-time records before and after glyoxal. *a*, Family of current time records in the control solution: 500 mM CsF, 5 mM NaF and 20 mM CHES buffer adjusted to pH 9.0. The external solution was filtered seawater. The currents were produced by potential steps in increments of 10 mV from –30 mV to +90. *b*, Effect of 5 mM of the trimeric dihydrate of glyoxal (Sigma) applied in the control solution for 15 min. The number of voltage steps has been reduced for clarity. The currents shown are produced by potential steps in increments of 10 mV from –10 mV to +40. The experiment was carried out at the Marine Biological Laboratory, Woods Hole, Massachusetts, on axons of *Loligo pealei*.

Fig. 2 Removal of inactivation by arginine-specific reagents. Thirty millisecond conditioning prepulses of various amplitudes were given before to a test pulse (+10 mV). The ratio of the test current for different conditioning potentials to the maximum test current at large negative conditioning potentials is plotted. *a*: ●, control values with an internal solution containing 400 mM KF, 100 mM TEABr, 5 mM NaF and 20 mM CHES buffer adjusted to pH 9.0; ■, same conditions after treatment with 15 mM diacetyl trimer for 45 min. *b*: ●, control internal solution was 500 mM CsF, 5 mM NaF and 20 mM CHES buffer to pH 9.0; ○, same conditions after treatment with 5 mM of the trimeric dihydrate of glyoxal. The trimer of 2, 3-butanedione was synthesised according to the method of Grossberg and Pressman¹⁴. A 15% aqueous solution of 2, 3-butanedione buffered to pH 8.0 with potassium phosphate was allowed to condense at constant pH for 48 h before use. This yields a solution of approximately 0.3 M trimer.

We also applied phenylglyoxal. A 1 mM solution of the reagent applied in a pH 7.3 internal saline produced a decrease in peak inward current without any removal of inactivation. Higher concentrations of phenylglyoxal led to a rapid and relatively complete removal of peak inward current, and a concomitant increase in leakage. Effects on inactivation in these conditions were difficult to determine.

Use of the third arginine reagent, 2,3-butanedione trimer, is complicated by the long reaction times necessary at pH 7.3. Fortunately, reaction at higher pH is more rapid^{9,14}. In squid, perfusing with a 15 mM solution of trimer in internal perfusate at pH 9.0 led to a 50% reduction in peak inward current and substantial removal of inactivation (Fig. 2a).

None of the effects of application of the reagents is reversible. The reduction of peak inward current for all the reagents and the removal of inactivation for glyoxal and the diketone trimer were not altered even after repeated changes of internal perfusion solution free of the reagents.

The previous results made arginine (or possibly lysine) a likely component of the Na⁺ inactivation mechanism. To test the possibility that arginine might actually be the blocking residue of the inactivation molecule, we completely removed inactivation by treatment with Pronase², and then

Table 1

Amino acid	Effect	Fraction of sodium* current after treatment
Arginine	+	0.76 ± 0.07 (n = 6)
Lysine	0	0.96 ± 0.06 (n = 6)
Aspartic acid	0	1.00 (n = 1)
Glutamic acid	0	1.00 (n = 1)
Glycine	0	1.03 ± 0.06 (n = 3)
Histidine	0	1.08 ± 0.07 (n = 4)
Tyrosine†	0	1.01 (n = 2)
Asparagine	0	0.99 (n = 2)
Glutamine	0	0.99 ± 0.07 (n = 4)

Internal solution contained (mM): CsF 500, HEPES 20, Na 5 + amino acid 50. External solution was filtered seawater.

*Ratio of inward current in the presence of the amino acid to the inward current in the absence of the amino acid (for a voltage step to 0 mV).

†Tyrosine was applied as a 5 mM solution.

internally applied various amino acids. Table 1 shows that of the amino acids tested only arginine shows a significant blocking ability. Notably, lysine produces no significant blocking effect. We feel that the reason arginine produces a simple blockage of current rather than a time-dependent reduction of current similar to normal inactivation is due to the relatively mobile character of the free amino acid. This blockage is analogous to the effect of tetraethylammonium (TEA) and its higher analogues on the sodium channel⁶. TEA equilibrates with the sodium conductance mechanism so rapidly that no time dependence is observed. TEA analogues with a hydrophobic side chain equilibrate at a much slower rate, producing a time dependent reduction in current.

With this analogy in mind, the possibility that arginine could be the blocking residue was tested further by internally applying the polypeptide, polyglycyl arginine amide,

Fig. 3 Effect of polyglycyl-*N*-acetyl arginine amide on outward sodium currents in a fibre, without inactivation. Axon bathed in Tris-HCl 450 mM, MgCl₂ 50 mM, CaCl₂ 10 mM, pH 7.9; internally perfused with 250 mM NaF, 500 mM sucrose, 5 mM Tris-HCl, pH 7.3; temperature 5 °C. The figure shows currents in response to voltage clamp pulses that took the membrane potential to the values indicated below from a holding potential of -60 mV. *a*, Current records for pulses to -30, -10, 10, 30, 50, 70 and 90 mV. *b*, Current records after perfusing the axon for 12 min with Pronase dialysed overnight against EGTA (final concentrations: Pronase, 1 mg ml⁻¹, EGTA 1 mM). Membrane potential during the pulses: -30, -10, 10, 30, 50, 70, 90, 110 and 130 mV. *c*, Seven minutes after the records in *b* were taken, the axon was internally perfused with polyglycyl-*N*-acetyl arginine amide (approximately 0.1 mM molecular weight 10,000) and the records shown taken 5 min later. Membrane potential during the pulses: -30, -10, 30, 50, 70, 90, 110 and 130 mV. The polyglycyl-*N*-acetyl arginine amide was synthesised by coupling polyglycine of molecular weight 5,000 to 10,000 (Sigma) with *n*-acetyl-arginine (Sigma) using a water-soluble carbodiimide as a coupling agent¹⁸. Separation of the desired peptide from unreacted components was accomplished by chromatography in Sephadex G-10, followed by ion exchange in CM-Sephadex. The experiment was carried out using axons of *Loligo forbesi* at the Marine Biological Association, Plymouth, UK. Similar results were obtained with a longer polyglycyl arginine derivative (molecular weight 20,000).

in an axon which had previously been treated with Pronase to remove inactivation. The results suggest that this peptide can mimic sodium inactivation (Fig. 3).

In axons treated with Pronase, perfused internally with sodium fluoride containing the peptide and bathed in sodium-containing artificial seawater, time dependent block of both the inward as well as the outward sodium currents was observed (E. Rojas and B.R., unpublished).

When considering these results, special attention must be given to the specificity of the reagents used to react with the presumptive arginyl residue. For each reagent used, the only significant reaction besides that with guanidino moieties is with amino groups. The reaction of all the reagents with amino groups is much slower and less complete than with arginine⁷⁻⁹.

Thus, the reaction kinetics of the reagents make reaction with lysine seem less likely than arginine. If the reagents are actually attacking a blocking residue acting as either a physical or electrostatic 'plug' during inactivation, the results of the amino acid and polypeptide application make the reaction with arginine even more attractive since lysine seems to be unable to block the sodium channel.

The reduction in the peak inward current after application of the reagents may be due to several things. Of course, the reagents may be directly reacting with the sodium conductance mechanism in some unspecified way. Alternatively, each of the reagents may be capable of cross-linking reactions¹⁸. This might lead to an occasional reaction where the blocking residue of the inactivation molecules is cross-linked while in a blocking position, with a consequent reduction in sodium conductance.

We can consider these results in the context of the models already suggested^{5,6}. Both models require a charged group that is 'tethered' to the membrane. The charged group is capable of blocking open sodium channels and consequently producing inactivation. In the model of Rojas and Rudy, it is strongly suggested that the charged moiety is an arginyl residue in a peptide chain. Our data with the amino acids and polypeptide suggest that an arginyl residue could actually be the blocking component, but that lysine could not.

But, whatever the actual mechanism of inactivation, our results with glyoxal and diacetyl trimer strongly suggest that an arginine residue must be an important functional part of the inactivation process.

Photoreceptor electric potential in the phototaxis of the alga *Haematococcus pluvialis*

THE nature of the primary processes in the photoreceptor and the mechanism of their coupling with the mechanical response of the flagella are the most important and, at the same time, the least investigated problems of the phototaxis in flagellates¹⁻⁵. It has been suggested that the transduction of the light stimulus in phototaxis might involve bioelectric processes^{4, 6-9}, but no direct experimental evidence supports this hypothesis. The bioelectric control of the locomotor responses to light^{10,11}, mechanical¹² or electrical¹³ stimulation has been found in ciliates, but they do not possess the orientated phototactic response mechanism¹⁴ of flagellates. Now we demonstrate the photoinduction of electric potentials related to phototaxis in the unicellular flagellated alga *Haematococcus pluvialis*. Photo-stimulation evokes a graded receptor potential which gives rise to a regenerative potential dependent on the presence of extracellular calcium ions.

Insertion of a microelectrode rapidly damages the cell, hence electrical potentials were registered extracellularly. In the developed technique the cell was sucked (under microscopic control) into a tip of a glass micropipette (Fig. 1), causing two parts of the cell surface, the inside and outside, to become electrically isolated by the glass of the pipette (shunt resistance, up to 100 MΩ) thus enabling measurement of the electrical potential difference (PD) between them. The micropipette and the chamber in which its tip was located were filled with the same solutions (usually growth medium) and connected by KCl bridges and calomel electrodes to the amplifying and registering equipment similar to that described earlier^{15,16}. A signal was considered positive if the inner part of the pipette had a positive potential in reference to the potential of the chamber. The time resolution of the system was about 1 ms.

For actinic illumination, a flash xenon lamp (flash duration, less than 1 ms) or a halogen incandescent lamp provided with an electrical shutter (opening time, about 1 ms) were used. The intensity of a light stimulus was measured by a thermopile or a calibrated photodiode and was changed from 10² to 10⁶ erg cm⁻² s⁻¹ by neutral light filters. The measurements were carried out at room temperature using a water infrared filter.

The cells of *H. pluvialis* were grown at 20° C under constant illumination with fluorescent lamps (500 lx) in a medium containing 1 mM KNO₃, 0.4 mM K₂HPO₄, 0.3 mM MgSO₄, 0.3

mM Ca(NO₃)₂, and a standard solution of trace elements, and 3-7-d-old cultures were used.

The sucking of a cell into a micropipette leads to its slight deformation, but even after a 2-3-h experiment the cell regained its normal motility and a phototactic ('stop') reaction after being released from the pipette. In the dark or under red light illumination, there is no PD between the chamber and the inside part of the micropipette separated by the cell. On 1 ms flash illumination with white or blue-green light, a fast transient PD between the two parts of the cell surface (inside and outside the pipette) is generated (Fig. 2a). This primary photoinduced potential difference, PPD, comprises a fast rise of PD and its slower drop to zero. The response is graded, both the amplitude and the rate of the potential changes rising with the increase of light intensity.

Fig. 2 Kinetics of photoinduced electric potential difference (PD) between the two parts of the cell surface, the inside and outside of the pipette. The arrows mark the moment of a flash (for *a* and *c*) or of a switching on of continuous light (for *b* and *d*). An upward movement of the traces means an increase in potential inside the micropipette. Calibration: 2 mV and 100 ms. *a*, The posterior part of the cell is inside the pipette for *a*, *b*, *c*. Primary PD induced by 1 ms flash of three different intensities (1, 5 and 12 relative units for curves 1, 2 and 3, respectively). *b*, PD induced by continuous light of different intensity (1 and 8 relative units for curves 1 and 2, respectively). At the intensity exceeding a threshold level, primary PD becomes superimposed by a secondary regenerative response (curve 2). *c*, Effect of 3 mM azide on photoinduced PD. 1, Before the addition of azide; 2, 30 s after azide addition; 3, after the removal of azide from the chamber by a fresh solution. *d*, The same as *b*, but the anterior part of the cell is inside the pipette.

Fig. 1 Scheme of a cell fixation in a suction micropipette and extracellular potential difference registration. 1, Cell; 2, tip of the micropipette; 3, calomel electrode connected to the interior of the micropipette; 4, calomel electrode connected to the chamber; 5, amplifier; 6, oscilloscope.

When the intensity and/or the duration of a light stimulus exceed some threshold, the PPD becomes superimposed by a regenerative electric response (RR) (Fig. 2b). This spike-like signal has a two-wave form and usually one of the waves (positive or negative) dominates. Its amplitude reaches a constant level within a narrow range of rising stimulus intensities. Further light intensity increase leads to the shortening of the lag-period of RR from 60 ms to 5 ms. The blue-light induced RR has a refractory period of about 0.5-1.0 s. The appearance of the blue-light induced spike can be stimulated by the red background illumination or by the increase of the frequency of blue flashes (from 1 to 20 per min), while the prolongation of a dark period leads to the disappearance of RR. These features of the spike-like electrical signal allow its separation from PPD.

RR is sensitive to poisoning by heavy metals or to the removal of Ca²⁺ ions by EDTA. Both factors also affect PPD, but to a much lesser degree. Spontaneous spikes can be sometimes

observed in the dark or under constant illumination. Their complex kinetics is similar to that of the photoinduced signals.

We believe that RR reflects the excitation of the whole cell membrane in a similar way, perhaps, to that found in ciliates^{11,13}. It is noteworthy that removal of Ca^{2+} also blocks the phototactic response (stopping, reversed locomotion) of *Chlamydomonas*⁹. Thus the RR is likely to play a significant part in phototaxis.

PPD has no (or less than 1 ms) lag-period. Its initial rise rate depends linearly on the light intensity up to $10^8 \text{ erg cm}^{-2} \text{ s}^{-1}$, the rise time being not more than 5 ms at this intensity. In contrast to this, the amplitude of the signal has a nonlinear light dependence and a tendency to saturate at high intensities. The PPD signals can reach 5–7 mV and can be reversibly inhibited by azide (Fig. 2c).

It was found that the sign of PPD is determined by the orientation of the cell in the pipette. The positive signals were registered in all cases when the posterior or lateral part of the cell was sucked into the pipette (Fig. 2a, b, c). If the same cell was fixed in the pipette so that the anterior, flagella-bearing part was in the pipette, signals of negative polarity but similar form were observed (Fig. 2d). This observation suggests that the anterior zone of the cell becomes negatively charged with respect to the other part of the cell surface under the action of light.

It is natural to suggest that the photoinduced polarisation of the cell is due to the asymmetrical location of the photoreceptor (an electric potential generator) in the cell membrane. Taking into account that the negative potential can be registered only from a small part of the anterior cell surface, one may conclude that the photoreceptor is located in this part of the cell, has a small size and generates the positive potential inside the cell with respect to the outer space under the influence of light. A simple equivalent scheme of the extracellular measurements of the potential can be proposed (Fig. 3). The scheme does not have capacity elements and cannot be used to describe the kinetics of the signals.

The anterior (a) and posterior (p) parts of the cell with transmembrane resistances R_a and R_p , respectively, are externally separated by the shunt resistance R_{sh} . The resting potentials (E_m) of the anterior and posterior membranes compensate one another in the dark. On illumination, the photoreceptor in the anterior part of the cell membrane generates an electrical potential E_r which is measured across R_{sh} as the PD. E_r can be determined if R_{sh} , PD and R_p are known. It was found that the light-induced voltage rises linearly with increase in shunt

Fig. 3 Simple equivalent scheme of the extracellular registration of the transmembrane receptor potential (see text). p and a, Posterior and anterior parts of the cell surface (inside and outside the pipette); R_p and R_a , the resistances of the posterior and anterior parts of the cell membrane; E_m , transmembrane potential in the dark; E_r , photoinduced receptor potential; R_{sh} , shunt resistance between p and a; G, voltmeter.

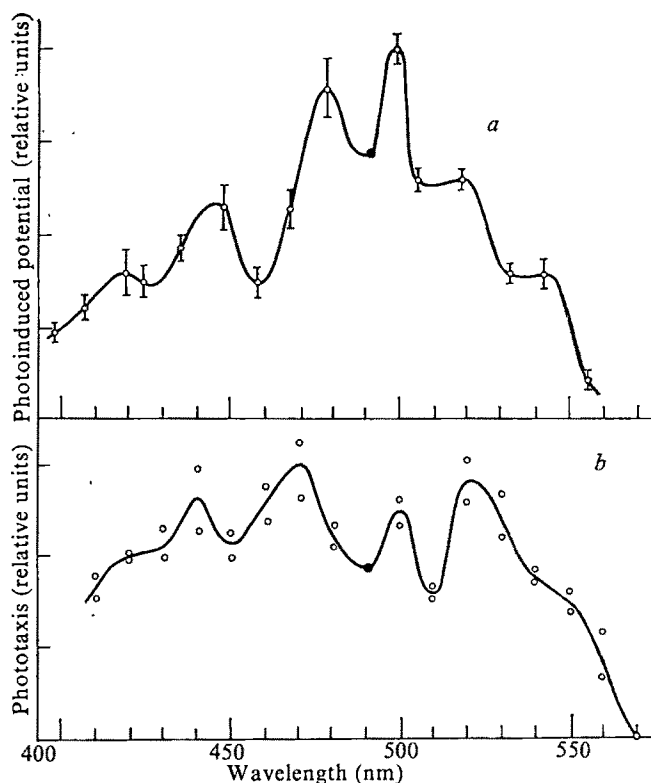

Fig. 4 Action spectra for the initial rate of PD rise (a) and the rate of phototactic cell accumulation in the lighted region (b). Spectral sensitivity at each wavelength was compared to that at 490 nm. Each point on curve a represents a mean value of 6–12 measurements $\pm \sigma$ corrected for the number of incident quanta. Spectrum b was measured under the conditions of equal no. of incident quanta at each wavelength.

resistance (measured as a difference between the resistance of the pipette with the cell and that without the cell) as the cell is sucked into the pipette. With R_{sh} of $10^8 \Omega$, PD is 3.5 mV. Assuming that the specific membrane resistance of the cell membrane has an average value of about $2 \times 10^4 \Omega \text{ cm}^2$ (refs 17, 18), R_p is $1.4 \times 10^9 \Omega$ for a spherical cell 30 μm in diameter. For these values, the light-induced transmembrane potential E_r is about 50 mV. Because of the changes in the geometry of the cell in the pipette and of the possible deviations of the value of the specific membrane resistance from the accepted average, this calculation of E_r is a rough estimate.

It was found that only the blue-green region of the spectrum is efficient in the generation of the described potentials. The red and infrared light ($\lambda > 630 \text{ nm}$) have no effect, even at the intensities 3–4 orders of magnitude higher than the usually effective intensities of the blue light. The action spectrum for the rate of the PPD rise was measured with the use of interference filters (band pass, 10 nm) and was compared to the action spectrum of phototaxis of this organism (Fig. 4). For the net phototaxis action spectrum measurements, the equipment similar to that described earlier by Lindes *et al.*¹⁹ was used. The kinetics of the cell accumulation in the actinic zone was monitored by a testing (measuring) beam ($\lambda = 750 \text{ nm}$). The intensity of the monochromatic actinic light at each wavelength (band pass, 5 nm) was measured and equalised in a number of incident quanta before each kinetic curve was recorded. The initial rate of the cell accumulation in the illuminated zone was taken as a criterion of phototaxis (phototactic index)²⁰. As seen from Fig 4, the action spectra of the PPD generation and the net phototaxis are similar. This points to the generation of the described potential by the receptor pigment(s) of phototaxis.

Rapid (less than in 30 s) and reversible inhibition of the electrical signal by azide (3 mM), known as an efficient and reversible inhibitor of phototaxis²¹, also indicates that there is

close connection between the potential generation and phototaxis. PPD, however, is not sensitive to 3-(3,4-dichlorophenyl)-1,1-dimethylurea, the inhibitor of photosynthesis, in usually efficient concentrations (10^{-5} M).

The time characteristics of the electrical signal, its dependence on the intensity and spectral composition of the actinic light, the localisation of the photoreceptor, the character of the inhibitors' action, and others suggest that the photoinduced potential is a photoreceptor potential of phototaxis. The mechanism of the potential generation is not yet clear, and may be based on changes in permeability for ions, as well as active electrogenic processes. Also, the receptor potential may affect the action of flagella directly or through the secondary regenerative response. To solve these problems further experiments are necessary.

Stimulation of brain membrane protein phosphorylation by calcium and an endogenous heat-stable protein

THE important role of Ca^{2+} in the physiology of the nervous system is well documented^{1,2}. However, the biochemical mechanisms underlying certain of its physiological effects, such as stimulus-secretion coupling^{3,4} and synthesis of catecholamines^{5,6}, have not yet been elucidated. Calcium has been implicated in several biochemical reactions of potential importance to synaptic function. Thus, calcium and a heat-stable calcium-binding protein activate the cyclic nucleotide phosphodiesterase from mammalian brain^{7,8}. The calcium-dependent regulator (CDR) from porcine brain⁹, bovine heart¹⁰ and bovine brain¹¹ has been purified and characterised. CDR seems to be a calcium receptor as it binds calcium strongly and specifically. There is evidence that a CDR· Ca^{2+} complex is the true activator of cyclic nucleotide phosphodiesterase¹²⁻¹⁴. A detergent-solubilised preparation of brain adenylate cyclase can also be activated by this calcium-binding protein¹⁵. Calcium stimulates protein phosphorylation in both intact^{16,17} and lysed^{18,19} synaptosomes and this cyclic nucleotide-independent mechanism may mediate or modulate some of the intracellular effects of Ca^{2+} on the function of presynaptic nerve terminals. We report here that calcium-dependent phosphorylation of synaptosomal membrane fractions from rat cerebral cortex requires an endogenous protein factor present in the synaptosomal cytoplasm. Calcium stimulated phosphorylation is lost on purification of synaptic membranes and can be effectively recovered by reconstitution with either the synaptosomal cytoplasm or with a purified preparation of CDR. Thus, regulation by calcium of calcium-dependent protein kinase activity

may be mediated physiologically by the calcium-binding protein postulated to regulate cyclic nucleotide phosphodiesterase and adenylate cyclase.

The effect of calcium on endogenous protein phosphorylation in lysed synaptosomes and in synaptic membranes is shown in Fig. 1. Synaptosomes obtained from rat cerebral cortex were lysed by hypo-osmotic shock and assayed for incorporation of ^{32}P -phosphate from γ - ^{32}P -ATP into protein (Fig. 1, lanes 1 and 2). Calcium caused a marked stimulation of endogenous protein phosphorylation. A net increase in ^{32}P -phosphate incorporation into a number of protein bands was observed, with those having molecular weights of about 51,000 and 62,000 showing highest levels of incorporation. Similar patterns of stimulation by calcium have been observed by DeLorenzo and Freedman^{18,20}, though much higher calcium ion concentrations seem to be required in their system.

The calcium-dependent phosphorylation observed in assays containing both synaptic membrane fractions and synaptosomal cytoplasm (that is, lysed synaptosomes) is lost on

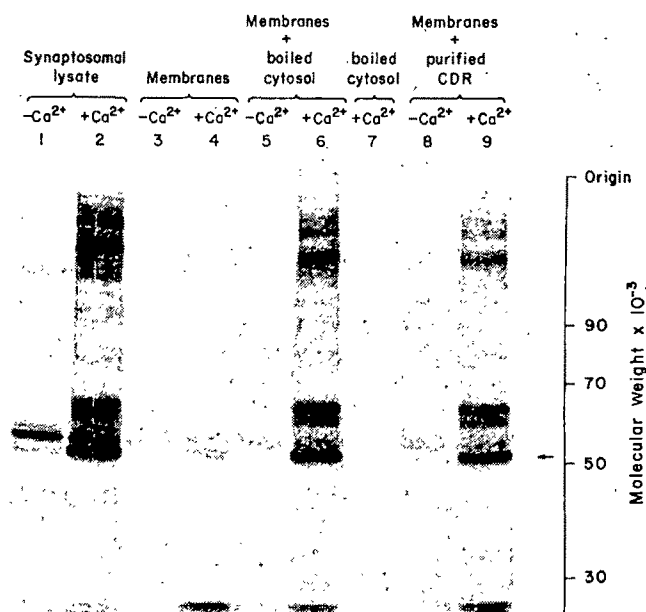

Fig. 1 Effect of Ca^{2+} , synaptosomal cytoplasm, and purified CDR on endogenous protein phosphorylation of brain membranes. Male Sprague-Dawley rats (150-200 g) were killed by decapitation and the cerebral cortex used for preparation of synaptosomes (P2) by minor modification of the method of Gray and Whittaker²⁸. The suspension of synaptosomes obtained from 2 g of cerebral cortex was subjected to osmotic shock by homogenisation in 10 volumes of ice-cold water (15 ml) and kept on ice for 30 min to optimise lysis. The synaptosomal lysate contained 2.5 mg protein ml^{-1} . Total membranes were obtained from lysed synaptosomes by centrifugation at 150,000g for 30 min. The released synaptosomal cytosol (0.7 mg ml^{-1}) was removed, heated at 95-100 °C for 5 min, and used as the source of activator. The pellet was resuspended in 15 ml of 5 mM Tris-HCl (pH 7.0), centrifuged as above, and again resuspended in 15 ml of 5 mM Tris-HCl (pH 7.0). This resuspended pellet (1.7 mg ml^{-1}) served as the source of activator-deficient membranes. Membranes stored at -20 °C were stable for about 1 month. CDR was purified to homogeneity by the method of Teo *et al.*¹⁰. The reaction mixture for assay of endogenous protein phosphorylation (final volume, 100 μl) contained: 50 mM PIPES buffer (pH 7.0), 10 mM MgCl_2 , 1 mM dithioerythritol, 0.2 mM EGTA (minus calcium) or 0.2 mM EGTA+0.5 mM CaCl_2 (plus calcium), 5 μM γ - ^{32}P -ATP (3.0 - 7.0×10^4 c.p.m. pmol^{-1}), and, where indicated, 50 μg lysed synaptosomes, 34 μg membranes, 14 μg boiled cytosol and 0.25 μg CDR. The reaction was initiated by addition of the γ - ^{32}P -ATP after preincubation for 30 s at 30 °C. Incubation was carried out for 10 s, the reaction terminated by addition of 50 μl of an 'SDS-stop solution', and a 75 μl aliquot of the sample analysed by SDS-polyacrylamide gel electrophoresis and autoradiography as described previously²⁹. Using procedures described elsewhere¹⁷, radioactive bands were found to be due to incorporation of ^{32}P -phosphate into protein (by phosphomonoester linkage) rather than into lipid or nucleic acid. Results similar to those shown here were obtained when more purified preparations of synaptosomes were used.

preparation of cytoplasm-free membranes (Fig. 1, lanes 3 and 4). This phenomenon was not due to inactivation of the calcium-dependent kinase activity during experimental manipulations as it could be regained by addition of an amount of synaptosomal cytoplasm (Table 1) or boiled synaptosomal cytoplasm (Fig. 1, lanes 5 and 6; Table 1) commensurate with the amount of membrane protein present. The heat-stable factor in the cytosol which conferred calcium-dependent phosphorylation on washed membranes did not exhibit any endogenous phosphorylation (Fig. 1, lane 7), nor did it show any histone, protamine or casein kinase activity (data not shown).

The heat stability of the stimulating factor in the cytosol suggested a possible relationship to the calcium-binding protein that modulates activities of cyclic nucleotide phosphodiesterase and adenylate cyclase. Therefore, this calcium-dependent regulator was purified to homogeneity from bovine cerebral cortex by the method of Teo *et al.*¹⁰, in order to test its effect in the calcium-dependent protein phosphorylation system. Addition of this protein to washed synaptosomal membrane fractions restored calcium-dependent protein phosphorylation (Fig. 1, lanes 8 and 9). The pattern of phosphorylation obtained on addition of heat-treated synaptosomal cytoplasm was indistinguishable from that obtained on addition of CDR, suggesting that the two factors are functionally equivalent.

Stimulation of protein phosphorylation was dependent on the presence of both calcium and either the cytosol factor or CDR. Thus, calcium in the absence of boiled cytosol and boiled cytosol in the absence of calcium were ineffective, whereas addition of both calcium and boiled cytosol restored phosphorylation (compare lanes 3, 4, 5 and 6). Analogous results were obtained with CDR (compare lanes 3, 4, 8 and 9). The endogenous activator, like CDR, is extremely heat stable, non-dialysable, resistant to DNase and RNase, and sensitive to trypsin (Table 1).

CDR is present in synaptosomal cytosol of bovine and rat cerebral cortex and should, therefore, account for some of the activation seen by reconstituting membranes with synaptosomal cytosol. However, this does not exclude the possibility that other factors also present in the cytosol may be physiologically important regulators of the calcium-dependent phosphorylation reaction. Therefore, we have recently purified a protein from bovine cerebral cortex based on its ability to stimulate protein phosphorylation in activator-depleted membranes (in preparation). Only a single peak of activity was present throughout the purification procedure. This activity co-purified with the phosphodiesterase activator, suggesting that this endogenous

activator of the calcium-dependent phosphorylation system is CDR.

The calcium-dependent regulator seems to have a rather broad distribution in the animal kingdom²¹. Various mammalian and invertebrate tissues have been found to contain low levels of calcium-activatable phosphodiesterase and very high levels of CDR²¹⁻²⁶, leading many investigators to speculate that there must be other functions for this protein. Indeed, Kretsinger has postulated that all of the processes in which calcium functions as a second messenger are mediated by calcium-binding proteins with binding properties similar to those of CDR²⁷. The findings reported here demonstrate that calcium and CDR can affect protein phosphorylation directly, by stimulation of a calcium- and CDR-dependent protein kinase system, and suggest that this system may mediate some of the presynaptic actions of calcium. Calcium and CDR can presumably also regulate protein phosphorylation indirectly, by changing cyclic nucleotide levels by means of effects on cyclic nucleotide phosphodiesterase and adenylate cyclase activities.

Table 1 Characterisation of the cytosol factor

Addition to activator-depleted membranes	³² P-phosphate incorporated % of control
None	27
Untreated cytosol	100
Heat-treated cytosol	95
Dialysed cytosol	99
DNase-treated cytosol	99
RNase-treated cytosol	97
Trypsin-treated cytosol	28

Cytosol (14 µg) was preincubated in the presence of 50 mM Tris-HCl (pH 7.2), 1 mM MgCl₂ and, where indicated, DNase (50 µg ml⁻¹), RNase (50 µg ml⁻¹) or trypsin (10 µg ml⁻¹), in a total volume of 30 µl, for 60 min at 30 °C. Trypsin inhibitor (egg white) was then added at a final concentration of 25 µg ml⁻¹ to the trypsin treated sample. The cytosol factor remaining after these treatments was assayed for its ability to support endogenous protein phosphorylation of synaptic membranes (34 µg) using the reaction mixture described in the legend to Fig. 1. For quantitative determinations, the radioactive band at a molecular weight of 51,000 (see arrow, Fig. 1) was localised by autoradiography, cut out of the dried gel and counted by liquid scintillation spectrometry. Incorporation in the presence of untreated cytosol is taken as 100% and represents 17.3 pmol phosphate per min per mg membrane protein. DNase, RNase and trypsin + inhibitor (egg white) added to synaptic membranes without cytosol had no effect. Results qualitatively similar to those shown here were obtained with several other proteins bands.

The use of *Xenopus* egg cells to assay the mRNA of single cells

TRANSLATION of mRNA in egg cells and oocytes of *Xenopus laevis* Daudin has been shown to be very efficient for mRNAs from a variety of cells¹⁻⁷ and has uses in developmental biology, molecular biology and immunology⁸. We have also reported its use in cancer research⁹. One of the main disadvantages of this tool, however, is the fact that fairly extensive RNA extraction and purification procedures are required. In particular, in cases when different cell types are mixed, as in the case with immunologically active cells, it is almost impossible to obtain information about the activity of the separate cell types. Studies in this field are always dealing with, at best, highly enriched cell populations. Therefore we have looked for a method which avoids RNA extraction and purification, with the aim of being able to work with separate cells. We have tried to inject cell homogenates

directly into egg cells of *Xenopus*, and in the experiments reported here, we chose myeloma cells (LOU/M/WS1 rats with myeloma IR2 synthesising immunoglobulin E), because we could analyse the translation products easily and we could start with a relatively homogeneous cell population. Our results suggest that it is possible to study the translation products of single myeloma cells using this technique.

Fig. 1 *In ovo* synthesis of rat IgE. Female LOU/M/WS1 rats were infected with 0.5 ml myeloma IR2 cells (IgE-secreting myeloma¹⁰). After 7–9 d ascites was tapped and on average it contained 12.6×10^6 cells per animal. These were diluted 1:1 with Earle's balanced salt solution and layered on top of 5 ml Ficoll–Isopaque ($d=1.078$). After centrifugation for 30 min at 1,500g at room temperature¹¹, lymphocytes were taken from the top of the Ficoll–Isopaque cushion and washed twice with Earle's BSS. After the second washing, the cell suspension was divided into two equal parts, one for direct injection and one for RNA extraction. Both parts were frozen in solid CO₂ and used for injection and extraction the next day. Obtaining and handling of the egg cells of *Xenopus laevis* was as described earlier⁷, the only difference being the absence of actinomycin D in the incubation medium. Myeloma cells were suspended in double-concentrated injection medium, counted and homogenised. The final cell concentration corresponded to 5×10^6 cells ml⁻¹. One aliquot was diluted 1:1 with ³⁵S-methionine (Radiochemical Centre, Amersham, UK; specific activity 25 mCi mmol⁻¹) and 50 nl injected, containing 3×10^5 d.p.m. = 5 pmol methionine. A number of dilutions was then made of the cell homogenate (1:2, 1:4, 1:10, 1:20, 1:40, 1:125). Of each sample, 50 nl was injected per egg cell after 1:1 dilution with radioactive precursor. As a control, 50 nl of 1:1 diluted precursor was injected alone. RNA was extracted as described previously¹², yielding 0.16 ng total RNA per myeloma cell. Eggs were incubated for 16 h at 17 °C and homogenised in 400 µl PBS. The homogenate was taken up in a total of 800 µl PBS and centrifuged 30 min at maximum speed in a Spinco 50Ti rotor at 4 °C. To 100 µl of the clear supernatant 5 µl absorbed goat anti-rat IgE was added. After incubation at 37 °C for 15 min, 100 µl of rabbit anti-goat IgG was added and the mixture was incubated at 37 °C for a further 15 min. After overnight precipitation at 4 °C the pellets were spun down in an Eppendorf centrifuge 3200 and washed thrice with cold PBS. The final pellet was suspended in 100 µl of a buffer containing 0.1 M Tris-glycine pH 8.3, 2% SDS, 5 mM 2-2-mercaptoethanol, and counted on Whatman 3 MM filter paper disks after drying in a Nuclear Chicago Liquid Scintillation Counter (efficiency ~ 70%). *a*, Radioactivity precipitable with anti-IgE after subtraction of the control value (300 d.p.m.). ●, Disrupted cells injected; ○, Crude RNA injected. In addition to the specific precipitation, a total, 10% trichloroacetic acid (TCA) precipitate of every sample was counted. *b*, Efficiency of translation expressed as the ratio of d.p.m. precipitable with anti-IgE over d.p.m. precipitable with 10% TCA. All experiments were done in triplicate.

The result of injecting several dilutions of cell homogenate are given in Fig. 1. Comparison of these results with those obtained after injection of a cold phenol RNA preparation shows no difference in response at greater dilutions. We conclude, therefore, that *in ovo* synthesis of IgE continues at the same rate following injection of RNA or cell homogenate of equal cell numbers, up to a maximum at about ten cells. At higher concentrations, however, a large decrease in specifically precipitable radioactivity is found after injection of cell homogenate, whereas this amount is almost constant after injection of RNA. The decrease is not caused by a general inhibition of translation by substances in the cell homogenate—as confirmed by plotting the efficiency, expressed as the ratio of radioactivity precipitable with anti-rat IgE to TCA-precipitable radioactivity (Fig. 1*b*). Clearly, only the specific translation is inhibited at increasing cell number. Purified, deproteinised RNA does not show inhibition to this extent. Therefore, this phenomenon may depend on protein(s). The inhibitors do not interfere with the translation machinery itself, since the total TCA-precipitable radioactivity is unaffected. The results show the presence in the myeloma cell homogenate of a substance(s) that specifically inhibits the translation of injected RNA. The source of this inhibitory material is uncertain, but the fact that greater concentrations of cell homogenate are required to effect inhibition could indicate that it is derived from other than myeloma cells. Since our cell homogenate was prepared from cells in the ascites, it is also very likely to contain material from other cells. We did not determine which cell type could be responsible for the observed inhibition.

Maximum efficiency of translation is found after injection of the content of about ten cells. In another study with myeloma cells, saturation of the *Xenopus* translation machinery was found after injection of 0.9 ng A-rich-containing RNA⁸. If we assume that there was the same percentage of A-rich-containing RNA in the myeloma cells that we used, saturation in our experiments was reached after injection of comparable amounts of RNA.

Fig. 2 Electrophoretic analysis of the translation products of *a*, endogenous *Xenopus* mRNA and *b*, mRNA from IR2 myeloma cells. The position of unlabelled marker IgE (ref. 13), run in the same gel, is also indicated (*c*). Before electrophoresis, egg homogenates were treated with goat anti-rat IgE as indicated in Fig. 1. The precipitates were dispersed in a buffer containing 0.025 M Tris-HCl (pH 6.8), 2% SDS, 5 mM 2-mercaptoethanol and 10% glycerol and heated for 10 min at 100 °C. Electrophoresis was carried out at 50 V until the sample had passed through the spacer gel, after which 100 V was applied. Gels were stained with Coomassie Brilliant Blue R250 (0.2 g in 100 ml 7% acetic acid in methanol-water 1:1 v/v). After destaining in the solvent, gels were treated with DMSO–PPO, dried and placed in contact with RP Royal X-Omat X-ray film at –70 °C for 2.5 months¹⁴.

Fig. 3 Dilution experiment by coincubation with purified rat IgE. Before addition of goat anti-rat IgE as described in Fig. 1, the indicated amounts of purified rat IgE (ref. 13) were mixed with the samples. Further procedures were as in Fig. 1 and control values were subtracted. ●, Twelve cells injected per egg, ○, one cell injected per egg.

Electrophoretic analyses of the translation products with myeloma and endogenous RNA are shown in Fig. 2. Most of the radioactivity is found in those parts of the gel where the IgE marker bands are found, whereas in the control experiment, radioactivity was almost exclusively in the buffer front. Further proof of specific translation is given in Fig. 3, which shows that the precipitation of radioactivity with anti-rat IgE is diminished by coincubation with unlabelled purified rat IgE. The results of a similar experiment with the translation products after single cell injection are more variable, but they show the same tendency.

We conclude, therefore, that the *Xenopus* egg translation system makes possible study of the activity of a small number of cells, which can be selected under the microscope by micromanipulation and, as a result, can be very well defined. The minimum number of cells to be used will depend on the amount of messenger per cell, but in our experiments, we could even go as far as a single cell.

Another and, in our view, a very important advantage of our technique, is the fact that no extraction procedures are involved. Part of every RNA extraction is deproteinisation. As a result, masked messengers will contribute their products, whereas they would be inactive *in vivo*. Our method better preserves the native structure of the RNA and, therefore, gives better insight into the actual translational processes in the cell.

***In vitro* synthesis and characterisation of full- and half-genome length complementary DNA from avian oncoviruses**

RNA tumour viruses carry an RNA-dependent DNA polymerase which can transcribe the viral RNA genome into single-stranded and double-stranded DNA in detergent-disrupted virions^{1,2}. For several years since the discovery of this enzyme, only short DNA fragments of about 100-200 nucleotides long could be produced³. Recently, conditions have been described for the synthesis of possibly full-genome length complementary DNA (cDNA)⁴⁻⁶. The *in vitro* conditions described, however, were not well characterised and did not seem to be very efficient. We report here an efficient synthesis *in vitro* of half- and possibly full-genome length cDNA in avian oncoviruses. These two discrete species of cDNA were synthesised in large quantities. Furthermore, some of the half-genome length cDNA were found to form single-stranded circular molecules with a distinct secondary structure.

The Schmidt-Ruppin strain of Rous sarcoma virus (RSV) of subgroup D (SR-D) was used throughout the experiments. The similar procedures have also been successfully applied to several other strains of avian and murine oncoviruses. Growth of avian oncoviruses in secondary chicken embryo fibroblasts followed the published procedures⁷. The culture media were collected every 12 h. The viruses were purified according to the published methods⁸, and were used immediately for DNA synthesis as described in Fig. 1. We have previously observed that the optimum concentration of Triton X-100 used in the DNA synthesis varied for every virus preparation. It was therefore determined individually for every virus preparation. We also found that the minimum concentration of the viral proteins for efficient synthesis of large cDNA (molecular weight $> 1.5 \times 10^6$) was 1 mg ml^{-1} . At lower concentration, the efficiency of DNA synthesis remained the same, but the molecular weight of DNA products were usually less than 1×10^6 . In contrast to the published report⁹, we found that sodium pyrophosphate inhibited rather than enhanced DNA synthesis (data not shown).

The DNA products synthesised *in vitro* were analysed by using an alkaline sucrose gradient. As can be seen in Fig. 1a, 10-20% of the DNA synthesised had a sedimentation velocity greater than or equal to that of the denatured SV40 DNA marker (molecular weight 1.65×10^6). There were two distinct peaks of DNA products. The one with higher sedimentation velocity (peak I) comigrated with ³²P-35S viral RNA when electrophoresed in a formamide-acrylamide gel (Fig. 1b). This DNA was also shown by electron microscopy to be single-stranded linear DNA

molecules of 9–10 kilobases. About 90% of these DNA molecules could be digested with nuclease S1. After hybridisation with the viral 35S RNA, however, they became completely resistant to nuclease S1 (Table 1). Thus, this DNA peak represented single-stranded cDNA molecules, most of which were near full-genome length. They represented about 5–15% of the total cDNA made. At least 1 μ g cDNA of this species could be synthesised from 5 mg of the purified viruses.

The peak II DNA from the alkaline sucrose gradient had a sedimentation rate roughly equivalent to that of denatured SV40 DNA. This peak consisted of linear DNA molecules of 5–6 kilobases by electron microscopy. As with the full-genome-length cDNA, about 90% of the peak II DNA was sensitive to nuclease S1; after hybridisation with the viral 35S RNA, however, it became completely resistant (Table 1). Thus, they also represented complementary DNA sequences. In three independently prepared lots of cDNA from SR-D, circular single-stranded DNA molecules were observed besides linear DNA molecules (Fig. 2a and b). These circular molecules were very homogenous in size and the contour length of the circle was 5.63 ± 0.38 kilobases, which corresponded to a molecular weight of about 1.8×10^6 . A secondary structure resembling 'rabbit-ears' of distinct length (1.34 ± 0.23 kilobases if traced as completely duplex) and shape were also present in all of the circular DNA molecules (Fig. 2a and b). These circular molecules represented approximately 2% by number of the cDNA from peak II. We believe that these circular molecules were the product of the viral reverse transcription and not cellular contaminants, because no such molecules could be detected in the nucleic acids from the same SR-D virus preparation which had been subjected to the identical purification procedures, including RNase digestion and alkaline sucrose gradient sedimentation. In high formamide hybridisation conditions, these half-genome-size circular DNA could hybridise to the 35S viral RNA genome (for example, Fig. 2c). Unfortunately, such hybrids could only be detected at a very low frequency so that we could only tentatively map the hybrid region at the 5' half of the viral genome, starting at 3.5 kilobases from the 3' end of the genome. The

Table 1 Resistance of the *in vitro* synthesised DNA to nuclease S1

	After hybridisation without RNA	After hybridisation with RNA
Peak I	12%	100%
Peak II	12%	100%
Peak III	39%	85%
Peak IV	29%	79%

1,000 c.p.m. (specific activity $50,000$ c.p.m. μ g⁻¹) of the *in vitro* synthesised ³H-cDNA separated as in Fig. 1a with or without 1 μ g of the 70S viral RNA was used in each experiment. Hybridisation was carried out in 100 μ l of the solution containing 0.9 M NaCl, 0.09 M sodium acetate, 0.05% sodium dodecyl sulphate (SDS) and 1 μ g yeast RNA. The hybridisation mixture was heated at 120 °C for 1 min, chilled immediately and then incubated at 67 °C for 30 min. Afterwards, the hybridisation mixture was cooled gradually over a 12-h period. The nucleic acids were precipitated with 3 volumes of ethanol and then dissolved in 100 μ l of a solution containing 0.03 M sodium acetate buffer, pH 4.5, 0.0018 M ZnCl₂, 0.3 M NaCl and 200 units of nuclease S1 (Miles Laboratories)²⁰. The reaction mixture was incubated at 37 °C for 2 h and the percentage of the ³H-cDNA resistant to nuclease S1 was determined from trichloroacetic acid (TCA)—precipitable counts before and after nuclease S1 digestion.

difficulty in observing this kind of hybrid probably stemmed from the fact that, in the hybridisation conditions used, RNA·DNA hybrid is more stable than DNA·DNA duplex region which is responsible for the circle formation¹⁹. Therefore, most of the hybrids formed between the 35S RNA and the circular half-length cDNA would have become linear.

Thus we have made *in vitro* in high efficiency full- and half-genome-length cDNA from avian oncoviruses. It is interesting to note that the DNA molecules of molecular weight greater than 1.5×10^6 contain only complementary sequences. The shorter DNA fragments, on the contrary, contain both (+) and (−) strands as evidenced by their partial sensitivity to nuclease S1 after hybridisation with the viral RNA (Table 1). The full-length cDNA (peak I) was probably derived from reverse transcription initiated at the primer site to the 5' end of the virion RNA¹¹. The transcription complex may then have jumped to the 3' end of the same or adjacent genome and continued synthesis until

Fig. 1 Characterisation of the ³H-DNA products synthesised *in vitro*. The viruses purified from sucrose gradient⁸ were concentrated by sedimenting on to a 65% sucrose-D₂O cushion containing 0.01 M Tris-HCl, pH 7.4, 0.1 M NaCl and 1 mM EDTA before being used for DNA transcription. The endogenous reverse transcription was carried out in 4–8 ml of the reaction mixture containing 0.1 M Tris HCl, pH 8.0, 30 mM DTT, 3 mM magnesium acetate, 1 mM each of dATP, dCTP, and dGTP, 0.5 mM ³H-TTP (200 mCi mmol⁻¹, New England Nuclear), 1 mg ml⁻¹ of the purified viruses, and 0.02–0.03% of Triton X-100. The optimum Triton concentration was determined beforehand. The reaction mixture was incubated at 40 °C for 18 h. The DNA transcription was stopped by addition of EDTA to a final concentration of 12 mM. The nucleic acids were extracted with phenol three times and then treated with RNase A (50 μ g ml⁻¹) at 37 °C for 1 h. The ³H-DNA products were then further phenolised twice before being precipitated with 3 volumes of ethanol. a, Alkaline sucrose gradient sedimentation of the total DNA products. The ³H-DNA was pelleted by sedimentation at 20,000g for 15 min and then dissolved in 0.3 ml of a solution containing 0.33 M NaOH, 0.5 M NaCl and 0.02 M EDTA. The sedimentation was carried out in a 5–20% sucrose gradient containing the same solution at 40,000 rpm for 11 h at 20 °C in an SW41 rotor; 0.5-ml fractions were collected, and an aliquot of each fraction was counted. b, Fractions 3–6 in a were pooled, neutralised with 1 M acetic acid and then precipitated with 3 volumes of ethanol. The precipitate was dissolved in 40 μ l of phosphate-buffered formamide and electrophoresed in 2.5% formamide-polyacrylamide gel at 80 V for 18 h as described previously¹⁸. The ³²P-35S RNA of SR-D was included as a marker. 28S and 18S RNAs were run in a parallel gel. Δ , ³H c.p.m.; \circ , ³²P c.p.m.

Fig. 2 Electron micrographs of the cDNA synthesised *in vitro*. *a* and *b*, Fractions 8–12 in Fig. 1*a* were pooled and pelleted with ethanol. The DNA was dissolved in 50 μ l H₂O. Aliquots of the DNA were spread from 55% formamide, 0.06 M Tris-HCl (pH 8.5) and 0.006 M EDTA on to a hypophase containing 18% formamide, 0.01 M Tris HCl, pH 8.5, and 0.001 M EDTA. The arrows denote 'rabbit-ear'-like structures. *c*, Heteroduplex between circular cDNA and 35S RNA from SR-D. cDNA 20 μ g ml⁻¹ was hybridised to 35S RNA 10 μ g ml⁻¹ in a solution containing 80% formamide, 0.4 M NaCl, 0.01 M piperazine (pH 6.40) at 46 °C for 30 min. Aliquots of the hybrids were then hybridised to SV40-BrdU (that is, SV40 DNA on to which short poly(BrdU) tails have been added by terminal transferase¹⁹ at room temperature for 20 min in the presence of 0.25 M Tris and 0.025 M EDTA, pH 7.50). The final product was spread with the urea-formamide method described by Kung *et al.*¹⁵.

it reached near the 5' end again¹². Analysis of the DNA fragments of this full-length DNA cleaved by restriction endonucleases supported this interpretation (J. Taylor, A. S. Hsu and M.M.C.L., unpublished). It is not clear, however, where the DNA synthesis terminates. The half-length cDNA might be the result of early termination of transcription. Alternatively, it might have initiated from the same primer near the 5' end and then jumped to the middle of the RNA template. The latter interpretation is consistent with the observations that the early DNA products of reverse transcription contained sequences complementary to those in the middle of the 35S RNA^{13,14}. Preliminary heteroduplex studies suggested that at least part of the half-length cDNA was derived by the latter mechanism. Since the half-length circular cDNA molecules were tentatively mapped at the 5' half of the viral genome, they, too, were probably derived by the latter mechanism.

The formation of the 'rabbit-ear'-like structure in SR-D half-size circular DNA is also curious. This feature is similar to the dimer linkage structure of the RD-114 RNA genome in terms of size and shape¹⁵. We do not know whether it is all double-stranded in this region. Moderate denaturing conditions (55% formamide) did not dissociate this structure. Two possible mechanisms could account for the formation of such structure: (1) If these DNA molecules were the faithful transcripts of the viral genome it would suggest that there are inverted complementary sequences within the viral genome, spaced about 5.6 kilobases. A similar arrangement of genetic sequences has been observed in the genome of herpes simplex virus¹⁶. This arrangement, however, is unlikely since we did not observe such structures in full-length cDNA or 35S viral RNA. (2) If these half-size cDNA molecules represented the products

of aberrant DNA synthesis, for example, a hairpin synthesis at the termination site, then there might be homologous repeated sequences at both the initiation and termination sites for some linear half-size cDNA, which can then form a 'rabbit-ear'-like hybrid region. It has been demonstrated that small double-stranded circular viral DNA of molecular weight 3.4×10^6 could be found in the cells infected with Rous sarcoma viruses (ref. 17 and H. J. Kung, personal communication). The function and fate of these half-size circular viral DNA are unclear. They may be related to the half-size single-stranded circular cDNA of molecular weight 1.8×10^6 we observed in the endogenous reverse transcription *in vitro*.

This work was supported by grants from the NIH and the American Cancer Society. S. H. is a postdoctoral fellow of the Leukemia Society of America. We thank Cynthia Yung and Jean Wang for assistance.

Virus-like particles pathogenic to salivary glands of the tick *Boophilus microplus*

TICK-BORNE viruses are generally transmitted into the host's vascular system in infected salivary secretions¹, and it was to be expected that virus-like particles (VLPs) would be observed during an ultrastructural study of the salivary gland of the cattle tick *Boophilus microplus*. But it is surprising that some of these particles, which are described here, seem to damage the cytoplasm of infected cells, and in extreme cases even to affect the secretory competence of the salivary glands. In view of the economic and medical importance of these arthropods, viruses pathogenic to ticks could have a potential as biological control agents.

Adult female ticks were reared in the laboratory with stalled calves as hosts. VLPs were observed in three different generations collected for 6 months. Salivary glands were prepared as described elsewhere².

Secretory cells within the salivary glands of infected ticks contained large inclusions of regularly aligned VLPs (Fig. 1). Similar particles were not seen in either the synganglion or peripheral nerves from the same ticks. Less heavily infected cells were evident in which individual spherical particles were distributed randomly throughout the cytoplasm. The particles had a diameter of 42–45 nm and consisted of an electron-dense inner core (28–31 nm diameter) surrounded by a less dense outer rim. Some cells from infected tissues were characterised by cytoplasmic

areas which appeared light in intensity when compared with neighbouring regions. These 'plaque' regions were devoid of cytoplasmic organelles and contained both individual VLPs and groups of paracrystalline aggregates (Fig. 2).

In densely infected cells the particles were not observed as paracrystalline arrays but as individual particles which still had the electron-lucent outer rim and the electron-dense inner core (Fig. 3). Occasionally long crystalline filaments were observed in heavily infected cells; these filaments had an electron-dense outer layer and an

Fig. 1 Group of VLPs in granule-secreting cell from a type II acinus (50,555).

electron-lucent inner core—the reverse arrangement to that seen in the VLPs. It is not yet clear whether the filaments represent a different form of the particle (for example, a self-assembling aggregation of cell synthesised viral protein in excess of that required for virus-particle assembly) or if they are indicative of a different VLP. Similar filaments have been observed in close association with Colorado tick fever virus in cultured hamster kidney cells and in mouse brain cells⁷.

Fig. 2 Plaque region in the cytoplasm of an infected tick (33,000).

Densely infected cells were only seen in salivary glands from abnormally engorged ('plasma') ticks, that is ticks containing large volumes of haemolymph (100–150 μ l, compared with the 'normal' volume of 10 μ l). These 'plasma' ticks have been assumed to have fed on body fluids other than blood. Such an explanation would account for the low haemocrit value of the gut contents⁸ but not for the large haemolymph volumes. It is possible that the dense infections of VLPs observed in the salivary glands of 'plasma' engorged

Fig. 3 Two distinct types of VLP in a granule-secreting cell from a salivary gland of a 'plasma' engorged tick.

ticks reduce the secretory potential of the glands resulting in the accumulation of fluid in the haemocoel.

The presence of the particles described here has been established purely on morphological grounds. Studies directed at the confirmation of the viral nature of the particles and their pathogenic effects are continuing. Some viruses are known to be pathogenic to mites⁹ but so far none has been described in ticks.

I thank Drs J. D. Almeida and K. H. Harrap for helpful comments and the SRC for financial assistance.

Errata

In the letter by R. R. Kay, D. Garrod & R. Tilly, *Nature* 271, 58–60, the title should read 'Requirements for cell differentiation in *Dictyostelium discoideum*'.

In the letter 'Sequences and efficiencies of proposed mRNA terminators' by J. E. McMahon & I. Tinoco, Jr, *Nature* 271, 275, in paragraph 2 line 1, for give read given. In the text figure representing the sequence for two base pairs the dots should be centred between G–C and C–G.

Nature Index and Binders

The complete Index for 1976 is available, price £2.50 (UK), US\$5.00 (Rest of World). Copies of the 1975 index are still on sale, price £2.25 (UK), US\$5.00 (Rest of World).

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

Cellulose ion exchangers should be spherical too

DEAE-Sephacel[®] is

DEAE-Sephacel[®]
Total capacity: 1.4 meq/g
Wet diameter: 40–160 μ m

The spherical form of DEAE-Sephacel gives you easy, uniform packing without the generation of fines. It improves your results because it reduces zone broadening and ensures uniform, high flow rates. DEAE-Sephacel is reproducible from batch-to-batch.

No precycling is needed because DEAE-Sephacel is ready swollen. Its controlled macroporous structure, which is almost completely independent of pH and ionic strength, gives high protein capacities and excellent recoveries.

DEAE-Sephacel is the only spherical cellulose ion exchanger.

BIOLOGICAL NITROGEN FIXATION IN FARMING SYSTEMS OF THE TROPICS

edited by **A. Ayanaba**, *International Institute of Tropical Agriculture, Ibadan, Nigeria*, and **P. J. Dart**, *International Crops Research Institute for the Semi-Arid Tropics, Hyderabad, India*.

This volume is based on a Symposium held at the International Institute of Tropical Agriculture, in Ibadan, Nigeria, in October 1975. The Symposium's objectives included: an appraisal of the most recent studies relating to microbiological nitrogen fixation in tropical soils; consideration of methods of improving management of soils and crops in tropical farming systems to increase biological nitrogen fixation; Exploration of ways of concurrently improving both legumes and other hosts and their symbionts to enhance nitrogen fixation; and recommendations on the research needed and methods of collaboration.

ORGANIC REACTION MECHANISMS 1976

edited by **A. R. Butler**, *Department of Chemistry, University of St. Andrews*, and **M. J. Perkins**, *Department of Chemistry, Chelsea College, University of London*.

This twelfth volume, continuing the pattern now established for the series, surveys work on organic reaction mechanisms appearing in the literature dated December 1975 to November 1976. The aim has, as before, been to provide a concise and comprehensive coverage of work published in the period under review; where, at the time of writing, any particular results seemed of outstanding significance, these are described and discussed. The remainder are listed.

THE CHEMISTRY OF CYANATES AND THEIR THIO DERIVATIVES

edited by **S. Patai**, *Department of Organic Chemistry, The Hebrew University, Jerusalem, Israel*.

The Series 'The Chemistry of the Functional Groups' is planned to cover in each volume all aspects of the chemistry of one of the important functional groups in organic chemistry, in this case cyanates and their thio derivatives. The emphasis is laid on the functional group treated and on the effects which it exerts on the chemical and physical properties, primarily in the immediate vicinity of the group in question, and secondly on the behaviour of the whole molecule. The authors concentrate on important recent developments and on material which has not been well covered in other literature. (Series: The Chemistry of the Functional Groups). December 1977

0471 99477 4 632 pages £35.00/\$70.00 (part 1)

0471 99478 2 714 pages £37.00/\$75.00 (part 2)

0471 99425 1 1346 pages £72.00/\$145.00 (set)

SYNTHETIC REAGENTS Vol. 3: Diborane 2, 3-Dichloro-5, 6-dicyanobenzoquinone, Iodine, Lead tetra-acetate

General Editor: **J. S. Pizey**, *University of Aston in Birmingham*.

The plan used for the organization of the two earlier volumes in this series is repeated here. Four reagents, especially chosen for their current importance, versatility, and capability to cause major types of reactions, are reviewed in sufficient depth to provide a full understanding of their synthetic uses.

EFFECTS OF SOLAR ACTIVITY ON THE EARTH'S ATMOSPHERE AND BIOSPHERE

edited by **M. N. Gnevyshev** and **A. I. Ol.**

Translated from the Russian.

This collection of papers deals with the effects of the Sun on the Earth's climate, vegetation and animal life, including man. Particular consideration is given to the effect of solar activity on the troposphere. Newly discovered effects are dealt with: coagulability of blood, state of cardiac function, speed of human reactions, etc.

Territoriality and adaptation

Jared M. Diamond

Evolutionary Ecology. Edited by Bernard Stonehouse and Christopher Perrins. Pp. vi+310. (Macmillan: London, 1977.) £12.95.

THE late David Lack was a distinguished ornithologist noted for his pioneering evolutionary studies of ecological problems, such as ecological segregation among species, population regulation, territoriality, and reproductive rates. The present volume (not to be confused with the textbook of the same title, by Eric Pianka) consists of a collection of 21 chapters on topics related to Lack's interests, by former students, colleagues, scientific adversaries, and workers whom he influenced at a distance.

The chapters are grouped into four sections. The first five chapters discuss population regulation and territoriality, as illuminated by red grouse (A. Watson), wild rabbits (J. A. Gibb), and great tit (J. R. Krebs), or by controversies that pitted two of the authors (V. C. Wynne-Edwards and D. Chitty) against Lack. Next come four chapters that explore feeding adaptations and ecological segregation in Galapagos seabirds (M. P. Harris), marine Pelicaniformes (J. B. Nelson), seed-eating rodents (M. L. Rosenzweig), and common terns (I. C. T. Nisbet).

The longest section, on breeding adaptations and reproductive rates, consists of eight chapters discussing: arctic geese (I. Newton); great tit (H. N. Kluyver, J. H. van Balen, and A. J. Cavé); cooperative breeding among birds in general (C. H. Fry) and Argentine blackbirds in particular (G. H., C. E., and K. J. Orians); and clutch size in birds (D. F. Owen, C. M. Perrins and R. E. Ricklefs) and in the plant family Compositae (D. A. Levin and B. L. Turner).

The book concludes with four miscellaneous chapters, grouped under the heading of evolutionary adaptations, on systematics of echolocating swiftlets (Lord Medway and J. D. Pye), male group displays in *Chiroxiphia* manakins (D. W. Snow), animal communication systems (A. Zahavi), and big-bang reproduction in yuccas and agaves (W. M. and M. V. Schaffer).

To produce a memorial volume written by 21 different authors or sets

of authors, spanning a wide area of population biology, short enough to sell at a reasonable price, and of high scientific interest is at best a difficult task. The conflicting requirements of these goals weaken the book. Chapters average a frustratingly brief 12 pages in length. This prevents each chapter from giving a major overview of a field or exploring one problem in satisfying detail. The diversity of the content, and the paucity of cross-references between chapters, prevent the volume from developing a 'critical mass' on any single subject except nesting biology. Chapters vary considerably in level of insight. Some good chapters, such as those by Krebs and by Medway and Pye, seem to be so unrelated to the rest of the book that they would have been more effective if they had been published separately as journal articles.

The brevity of chapters is especially unfortunate because population regulation and reproductive rates are complexly determined by multiple factors, the relative importance of which varies with circumstances and with species. In the past, these subjects have often been approached in single-factor, single-species treatments, leading to running controversies that retarded progress. The sections on these two subjects would each have profited from a lengthy chapter synthesising the major factors into an overall scheme, reviewing each factor in detail, and giving examples of species or circumstances where each is important, to place the following chapters in perspective. Overall, I feel that this volume would have been more effective if it had focussed on a narrower span of population biology and consisted of fewer, longer chapters.

These remarks about the book as a whole do not detract from the interest of some chapters taken individually. Three examples must suffice. Watson reviews experiments and observations on the role of territoriality in Scottish red grouse. Between August and November of each year, males establish territories, and females pair with territorial males. The territory provides its owners with exclusive access to food in winter and spring, when food is scarcest and females are forming eggs. Most non-territorial males and unmated

females die of predation or of food scarcity by May. If territorial birds are shot, non-territorial individuals take over the territory, survive well, and breed. Brood size is determined in part by food supply mediated by egg quality formed by females: artificially fertilising the heather results in large broods. Implanting androgen hormone pellets in males makes them more aggressive, and results in their acquiring territories if initially non-territorial or enlarging territories if already territorial.

Newton discusses the extreme set of breeding adaptations that Arctic geese have evolved in response to the short summer. The geese arrive from their southern wintering grounds mated, the females fertilised and ready to lay within a week. Until eggs hatch, the adults survive mainly on fat and protein reserves laid down at wintering and migration areas, and they lose 17–50% of their initial weight. Number of eggs per clutch is greater for early-season clutches or in years with early snow melt. Breeding success varies enormously among years, so that the contribution of young birds to the autumn population may be as low as 1% or over 50%.

Zahavi illustrates the costs incurred by animal communication systems to achieve reliability and minimise cheating. Baby birds beg food from parents by displays that attract the parents' attention but could also attract predators. This risk 'blackmails' the parent into bringing food but inhibits fed nestlings from begging without cause and thereby diverting parents from unfed siblings. Arabian babblers live in groups which jointly defend a territory but of which only one, dominant pair breeds. The dominance hierarchy is maintained not by constant fighting but by a superficially altruistic display: dominant birds offer food to subordinates. That this display represents a dominance manoeuvre rather than altruism becomes clear when a subordinate individual offers food to a dominant one: this constitutes an act of rebellion and immediately provokes a fight. □

Jared M. Diamond is Professor of Physiology at the University of California Medical Center, Los Angeles, California.

Catastrophe theory

Catastrophe Theory: Selected Papers 1972-1977. By E. C. Zeeman. Pp. 675. (Addison-Wesley: Reading, Massachusetts, 1977.) Hardback \$26.50; paperback \$14.50.

THE strange union of mathematics, philosophy and methodology that has come to be called catastrophe theory sprang entirely from the totally original mind of René Thom. But its widespread popularisation, and its detailed application to the most diverse subjects, is largely the work of Christopher Zeeman. Their writings provide a perfect example of the contrast between the Gallic and Anglo-Saxon intellectual styles—while Thom is grandiose, poetic, elliptic, allusive, impatient with practical detail, sceptical about the possibility that his theory can be put to experimental test, Zeeman is pragmatic, painstaking, pedagogic, tirelessly fashioning ingenious falsifiable models of particular experimental situations, confident that catastrophe theory will form part of the mainstream of applied mathematics.

Thom's great book *Structural Stability and Morphogenesis* has been available since 1972, but Zeeman's most important work has appeared in conference proceedings or journals that are often difficult to obtain. Therefore this publication of a collection of twenty-two of his papers is a very welcome event—all the more so because Zeeman's work has recently come under strong critical attack. Now readers can study the original material and arrive at an informed opinion on the subject.

The mathematics gets steadily more difficult as the book progresses, the culmination being a proof of Thom's theorem (on the classification of singularities of gradient maps—the 'elementary catastrophes') which will be heavy going even for pure mathematicians. The bulk of the book, however, is devoted to applications of the theorem, and it is fortunate that it is possible to understand what it states, and to apply it, without knowing anything of the proof. In restricting himself to applications of the classification theorem (particularly the cusp catastrophe), Zeeman differs from Thom himself, whose speculations often invoke 'generalised catastrophes' the mathematics of which hardly exist as yet.

Space prevents my giving more than a brief indication of the range of Zeeman's applications. At the 'softest' level, they consist of dramatic pictorial encapsulation of the sense of proverbs using the cusp catastrophe; my favourite is "more haste less speed", where haste and skill are conflicting influences

(control parameters) on speed (behaviour variable). Then there are highly developed but still qualitative applications to biology, sociology and psychology. One example is the analysis of the development of the nervous disorder *anorexia nervosa* in terms of the cusp, the hysteresis of which, increasing with the 'splitting factor', models sufferers' sudden alternations between fasting and gorging; a clever invocation of the extra stable sheet of the butterfly catastrophe enables Zeeman to describe the way in which trance therapy can effect a seemingly miraculous cure. In two models (for the onset of prison riots and the impairment of driving skill by alcohol), quantitative data are presented; these are supposed to fit cusp catastrophes, but the points scatter so much that I suspect most readers will share my reaction of being impressed by Zeeman's ingenuity while remaining unconvinced by the evidence.

The 'hardest' applications are in physics. His use of the cusp to describe phase transitions is equivalent to Van der Waals' theory which is well known to fail at the critical point. Of this he

writes: "since density is an averaging device, the shape of the equilibrium surface very near the critical point is slightly distorted". By implication, this dismisses a flourishing area of theoretical physics aimed at understanding the deep reasons for this failure, and such naiveté is likely to cause physicists to think that catastrophe theory can make only trivial contributions in their subject; and that would be a pity. Two of the best chapters in this book, however, also concern classical physics. The first is the elegant and powerful summary of elastic buckling theory. The second is the masterly analysis of the stability of ships, where Zeeman blends the qualitative and the quantitative in an inimitable blend of orthodox naval architecture, topology, group theory and seamen's lore.

My opinion is that for readers interested in applications of catastrophe theory this is the best currently available introduction to the subject.

Michael Berry

Michael Berry is Reader in Physics at the University of Bristol, UK.

Ion-containing polymers

Ion-Containing Polymers: Physical Properties and Structure. By A. Eisenberg and M. King. Pp. 287. (Academic: New York and London, 1977.) \$27.50; £19.55.

THIS second volume in Academic's new series on Polymer Physics presents the first unified treatment of the physical properties and structure of *Ion-Containing Polymers*, which, according to the authors' definition, embraces polymer systems that contain ions and those to which ions can be attached. As one would expect, the book has been thoughtfully planned, no mean feat in a rapidly growing field. It is prefaced by a useful list of symbols; each chapter has a good bibliography; and there are separate author and subject indexes. The format is attractive and the print clear; the vast majority of figures are also excellent but good eyesight is needed to discern detail in a few; CGS units are used.

An introductory chapter describes current knowledge and gives a useful general classification scheme for ion-containing polymers subdivided into two main groups—polymers of low ion content, including Nafion-type systems and ionomers, and polyelectrolytes.

Chapter 2 deals with supra-molecular structure and glass transitions. Theories of and experimental

evidence for multiplet and cluster formation are treated in some detail, although not to mathematical excess. Clustering is seen to be akin to micro-phase separation and to result in many characteristics normally associated with crystalline systems.

Chapters 3 and 4 on the viscoelastic properties of homopolymers and copolymers respectively deal broadly with polyphosphates and silicates; low molecular weight salts in polar polymers and charge transfer complexes; polyelectrolytes; non-crystalline copolymers of high T_g (including perfluorinated ionics, rubber-based ionomers and crystalline copolymers mostly based on ethylene); and polyelectrolyte complexes.

Amongst the properties detailed are stress relaxation, creep compliance, modulus, mechanical loss, specific viscosity, zero shear viscosity, dynamic viscosity, normal stress coefficient and dielectric constant.

The final chapter (5), on configuration-dependant properties, discusses polyelectrolyte dimensions in solution, rubber elasticity, and dilute solution viscosity.

A valuable state-of-the-science book for the research worker in, or wishing to enter, the field of ion-containing polymers, as well as for the professional academic or industrialist.

P. L. Clegg

P. L. Clegg is Head of the Polymer Science Division of the Research Department at ICI Plastics Division, UK.

GENERAL MICROBIOLOGY

Fourth Edition

Roger Y. Stanier,
Edward A. Adelberg and
John L. Ingraham

The fourth edition of this well-known text retains the basic organisation of its successful precursors. Every chapter has been carefully updated, and in many cases rewritten, to take account of the new discoveries and interpretations in microbiology which have arisen in the intervening six years.

March 1977

hardcover £15.00, paperback £7.95

WATER RESOURCES AND LAND USE PLANNING

3-14 July 1978

Université Catholique de Louvain,
Louvain-la-Neuve, Belgium

NATO ADVANCED STUDY INSTITUTE

The Advanced Study Institute will analyse the relationship between water resources and land use in the framework of a multiobjective project. Hydrological, ecological and politico-legal aspects will be analysed, as well as the means available to solve large-scale problems. The course will be documented with different case studies.

Participants

The number of participants will be limited. There is no tuition fee for the course but participants will be required to pay BF 10,000 to cover the costs of lodging, reprints and social activities.

Scholarships are available on a selective basis to cover these costs and also travel expenses. Requests in this respect should be forwarded to the Director at the address indicated below.

Accommodation is available in the University town for the duration of the course.

Lecturers (to be finalized)

Dr. P. LACONTE, Director (Belgium); Prof. Y. Y. HAIMEs, Co-Director (USA); Dr. Y. EMSELLEM (France); Dr. M. HOLY (Czechoslovakia); Prof. P. H. JONES (Canada); Prof. G. KARADI (USA); Prof. E. VLACHOS (USA); Prof. E. WERTZ (Fed. Rep. Germany).

GENETICS, 2/e

Ursula W. Goodenough—Harvard University

Comprehensive, topically oriented text covers both classical chromosomal and molecular genetics, but emphasizes molecular. **New Edition has:**

- two new chapters ("Molecular Biology of Chromosomes" and "Recombination Mechanisms")
- extensive chapter – end bibliographies
- expanded problems
- Mendelian genetics presented earlier
- biochemical concepts placed in a more genetic context
- coverage of such new topics as: somatic cell, histocompatibility, mitochondrial genetics, plasmids, recombinant plasmids, and operator-promoter nucleotide sequences

Solutions/Instructor's Manual accompanies the text.

ISBN: 0-03-019716-3

896 pages

Cloth

1978

Notable Victorian naturalist

William Carmichael M'Intosh. By A. E. Gunther (Scottish Academic Press: Edinburgh, 1977.) £5.

THE way of the aspiring academic zoologist in the last century, not least in Scotland, was difficult. It usually involved initial training in medicine. Forbes, Wyville Thompson and Darwin failed to stay the course at Edinburgh. Perhaps W. G. M'Intosh was less fortunate, because graduation qualified him for 22 years' service in lunatic asylums before, in 1882, being appointed to the singularly designated chair of Civil and Natural History at St Andrews. There, however, he remained until 1917, retiring in his 80th year with fourteen years of activity still ahead.

Lifelong interest in marine biology began in childhood rambles on shores around St Andrews, from which his parents and sisters sent parcels of specimens during his years at the Perth District Asylum. He was a naturalist interested in comparative anatomy—highly conventional, holding Darwin in high regard as a naturalist but never really accepting evolution. His name will always be associated with the volumes of his Ray Society Monograph on British Annelids. Taxonomy was a subject to be treated with respect, and frivolities such as the naming, even by Ray Lankester, of a local sipunculid as *Golfingia macintoshi* were to be deplored.

He was involved in early activities

of the Scottish Fishery Board and in the controversies concerning the effects of intensified fishing. He maintained in his *Resources of the Sea* that nothing man did could materially diminish productivity. Pleas for a marine laboratory were answered by a generous donor from Sussex and the Gatty Marine Laboratory was opened in 1896. It was a minor tragedy when the small government grant was stopped and a greater one when his successor, formerly "my junior colleague at Dundee", D'Arcy Thompson, closed it. Already he had offended M'Intosh by participation in the much criticised activities of the International Council for the Exploration of the Sea. Indeed, apart from longevity, no two zoologists could have had less in common.

M'Intosh was a bachelor cared for by his sisters, the youngest of whom, responsible for early illustrations of his annelids, married Albert Gunther, Keeper of Zoology in the British Museum. It is this association that, following his *Century of Zoology*, has led A. E. Gunther to write this welcome account of his great uncle. Based on an unpublished autobiography and a wealth of documented information, it perpetuates the memory of a notable Victorian naturalist and a worthy fighter in what he believed to be right causes. With what happiness would he not view the present flourishing state of the Gatty Laboratory.

C. M. Yonge

Sir Maurice Yonge is Honorary Fellow in Zoology at the University of Edinburgh, Scotland.

Proteins in brain function

Protein Metabolism of the Brain. By A. V. Palladin, Ya. V. Belik and N. M. Polyakova. Pp. 335 (Plenum: New York, 1977.) \$42.

THERE is an active school of Soviet neuroscientists and Professor A. V. Palladin, who died in 1972 at the age of 87, was one of the pioneers. Palladin was particularly interested in the biochemical basis of brain function and this book reflects his interest in the role of proteins in the structure and organisation of the brain.

The book contains a description, usually in chronological sequence, of research into brain protein metabolism, with special reference to the contributions of Soviet scientists. The book was first published in 1972, in its original Russian, the English translation being completed in 1977. Because of this un-

fortunate lapse in time, it has become dated with the latest references being from 1970. Since then, there has been considerable progress in the effects of stress, hormones and drugs on brain protein metabolism. Moreover, our ideas on reutilisation of amino acids and turnover in the brain have undergone revision.

Not surprisingly, much of the basic information described under various subheadings—for example, "Brain Protein Metabolism in Ontogeny" or "Catabolism of Nerve Tissue Proteins"—can be found in more recent reviews dealing separately with these subjects. Nevertheless, the book does have the advantage of bringing together in one volume, the older literature on the varied aspects of brain protein metabolism, together with relevant Soviet literature. Even by today's standards, however, this is an expensive book.

Louis Lim

Louis Lim is Senior Lecturer in Neurochemistry at the Institute of Neurology, London, UK.

Eel biology

The Eel: Biology and Management of Anguillid Eels. By F. W. Tesch. Pp. 434. (Chapman and Hall: London, 1977.) £18.

WHEN I reviewed for these columns the original 1973 German version of this book, I expressed the wish to see it in English. This has now been granted, and Miss Jennifer Greenwood has given us a smooth and impeccable translation.

The sections concerned with endocrinology and sex determination have been brought up to date by Dr Ian W. Henderson. It is a pity that they were not expanded more. For example, two paragraphs on the interrenal organ (adrenocortical analogue) bulldoze over 19 references. Readers would welcome something more satisfying than the enumeration of papers, given that these topics are the growing points of current research on the eel. In fact, 50 out of 98 or so new (post-1972) references given are in the field of physiology. They cover also the feat of inducing sexual maturation of eels in the laboratory.

By contrast, it would seem from the references, that only Dr Tesch himself is currently engaged in the analysis of the eel's migratory behaviour.

The parts on fishery aspects remain the most detailed of the book. The continued interest in the economic value of the eel is shown by the fact that 26 post-1972 papers cited deal with fisheries and fish culture. This is well deserved by an animal that converts into protein for human consumption the insect larvae, worms and snails of rivers and lakes, that is, materials that could not be put to use in other ways. It is interesting to read of the persistent eel re-stocking operations in Eastern Europe and the commercial eel cultures in the Far East.

There have been minor adjustments in other parts of the book too; but no Table nor Figure has been replaced or added on the way. Even the prices of eels are still shown in Table 41 at their 1963 level!

The eel still presents fascinating and instructive problems for investigation. Its physiological versatility, its ambiguous sex determination, the intriguing migration patterns and separation of species, are only some of these. This good English version covering over 1,000 references on the subject, will be of great value to a much wider circle of biologists.

E. M. Pantelouris

E. M. Pantelouris is Reader in Genetics at the University of Strathclyde, UK.

obituary

Maurice Ingram

DR MAURICE INGRAM, former Director of the Agricultural Research Council Meat Research Institute at Langford and Professor of Applied Microbiology at the University of Bristol from 1968 to 1973, died suddenly at his home in Churchill, Avon, on Tuesday 15 November 1977.

Dr Ingram, who was born in Bradford in 1912, was educated at Bradford Grammar School and had a distinguished undergraduate career at Queens' College, Cambridge. After an early interest in botany he became increasingly concerned with food microbiology. His Ph.D. dissertation on *The Effect of Salts in Bacterial Respiration* was presented after joining the Low Temperature Station for Research in Biochemistry and Biophysics where he became Head of the Microbiology Department in 1951.

His early research on bacterial growth and metabolism led to studies of the involvement of pre- and post-slaughter stress factors in the quality and stability of cured products. This work became particularly significant during the second world war when he was engaged in problems of transporting meat and with its salvage after enemy action. In addition he directed research that led to the development of the special rations issued to Allied invading armies and to underground organisations in Europe. He later received the Haakon VII Liberty Medal from the Norwegian Government for his contribution to the partisan attack which destroyed the heavy water plant at Rjukan.

From 1947-49 he studied the bacteriology of whalemeat in an effort to utilise this wasted source of protein. His work on the preservation of concentrated orange juice, which involved travelling to Israel, Italy and Spain, led to the elimination of serious losses. Subsequently he led a team investigating the preservation of foods by ionising radiation. His earlier work again became important in further studies of curing, particularly with reference to food safety and the control of *Clostridium botulinum* by curing salts. He was also active in developing microbial specifications for foods.

In 1963 Dr Ingram was appointed the first Director of the projected Meat Research Institute and as he also became Director of the Low Temperature Station in 1965 he was involved in

the planning and recruitment for the two Institutes which replaced it, the Food Research Institute at Norwich and the Meat Research Institute at Langford. The latter was opened by H.M. the Queen in 1968 and Dr Ingram remained Director until 1973; an honorary degree of Doctor of Veterinary Medicine being conferred on him by the Ludwig-Maximilians University of Munich that year followed by the CBE in 1974.

He retired earlier than necessary to avoid ever-increasing administration which he did not enjoy. Retirement meant that he was able to devote himself more fully to science, and his international reputation ensured that he continued to travel widely, both in a personal capacity and as a consultant for the World Health Organisation. In July 1977 he received the Polish Society of Microbiology Gold Medal of Honour for "most outstanding services to microbiology"—a fitting tribute to a scientist of distinction and a man of great personal achievement.

A man of wide interests and ability he was an accomplished pianist, a keen botanist and, until recently, an enthusiastic and capable cricketer. He spoke French, German and some Norwegian, and read easily in those languages and in Danish. His colleagues will remember him as a man of great integrity, with a mind able to reduce complex questions to simplicity and to answer from a thorough understanding of the basic chemical and physical principles involved. His ability to evaluate arguments logically and to summarise complex discussions concisely made him especially valuable as a chairman at committees.

T. A. Roberts

William Bullerwell

DR WILLIAM BULLERWELL, FRS, FRSE, Deputy Director of the Institute of Geological Sciences, and Chief Geophysicist 1962-1977, died on 25 November aged 61.

After graduating with first class honours in physics in 1937 from Durham University (King's College) he took a further degree in geology, gaining the Lebour Prize for Field Geology, and began research in mining geophysics. This was interrupted by war service during which he

worked on experimental radar, and was mentioned in dispatches.

In the post-war period he joined the Geological Survey of Great Britain, now within the Natural Environment Research Council as part of the Institute of Geological Sciences. Following the pioneer geophysical work for the Survey by J. Phemister and W. F. P. McIntock, he initiated the programme of geophysics that is now a major part of the Institute's work.

In 1950 the Geophysics Division became responsible for collating all gravity data obtained in Great Britain and for its final publication as maps of Bouguer Anomaly: eight quarter-inch to one mile gravity overlay maps were published between 1954 and 1968. During the decade 1955-1965 he supervised the complete regional aeromagnetic survey of the United Kingdom which was published (following interim 1:250,000 scale Diagram Edition sheets) as colour-layered 'ten-mile' aeromagnetic sheets in 1965 and 1972. With his wife, Eileen, whom he married in 1942, and Dr and Mrs James Phemister, during summer vacations from 1953-1956 he carried out the first reconnaissance gravity survey of Scotland.

With the coming of the hydrocarbon search he became deeply involved in the government's research programme of hydrocarbon assessment and search on the continental shelf, especially in advising the Department of Energy. Recently he served on the Advisory Committee of Programme Management for Geothermal Energy of the Commission of European Communities, and from 1970 onwards he was much concerned with offshore prospecting in East Asia as representative for the Ministry of Overseas Development at the Economic and Social Commission for Asia and the Pacific Co-ordinating Committee.

Dr Bullerwell was an exceptionally kindly and generous man who had an encyclopaedic geophysical knowledge that was widely consulted and recognised; and he was elected FRS in 1972 (Council 1974-5) and FRSE in 1973. He served on numerous governmental, university and other professional committees, acting as Treasurer of the Geological Society from 1963-71, and as Chairman of the University of London's Advisory Board on Geophysics.

P. A. Sabine

announcements

Appointments

Lord Todd, O.M., President of the Royal Society has appointed the following Vice Presidents for the year ending 30 November 1977: **Dr B. J. Mason, C.B.**; **Sir Harrie Massey, Professor D. C. Phillips**; **Dr M. G. P. Stoker, C.B.E.**; **Professor P. Allen**; **Dr G. D. H. Bell, C.B.E.**; **Sir Angus Paton, C.M.G.**; and **Sir Peter Swinnerton-Dyer, Bt.**

J. L. van der Post, Director of the British Gas Engineering Station at Killingworth succeeds **Dr R. G. Allen, O.B.E.**, as Director of the Water Research Centre from February.

The following have been elected Emeritus Professors of the University of Bristol: **T. K. Ewer** in Animal Husbandry, **W. A. Gillespie** in Clinical Bacteriology and **R. F. E. W. Peel** in Geography.

Dr Fred Stratton, Director of the Blood Transfusion Service of the North Western Regional Health Authority to Professor (part-time) of human serology at Manchester University.

Awards

The 1977 Papers and Craftsmanship Premiums of the Gordon Radley Fund (Christopher Columbus Prize) awarded by the Post Office to scientists and engineers under 30 for published research work went to **Michel Eve**, **Dr Graham Davies**, **John Davies** and **Robert Walters**.

Michael Heidelberger of New York University, **Elvin A. Kabat** of Columbia and **Henry G. Kunkel** of Rockefeller University have shared the Columbia University's 1977 Louisa Gross Horwitz Prize for their research on the body's disease combating ability and its use in the diagnosis and treatment of disease.

The Paul Martni Prize (20,000 DM) for 1978 will be awarded by the Medizinisch Pharmazeutische Studiengesellschaft e.V., Humboldtstrasse 94, D 6000 Frankfurt. The award is intended to promote the development of scientific methods for the evaluation of clinical, pharmacological and therapeutic fields. Papers, which must be self contained and if published less than 2-yr-old, should be submitted before 30 April 1978.

On the move

Dr Martin Evans from the Department of Anatomy and Embryology, University College London to the Department of Genetics, University of Cambridge.

Dr Norman Shaw from Microbiological Chemistry Research Laboratory, University of Newcastle upon Tyne, to visiting professor in the Department of Chemistry, Washington University.

Dr John Walker from Physics Department, University of Reading and Groupe de Physique des Solides de l'Ecole Normale Supérieure, Université Paris VII, to Quantum Science Corporation, 16 Charles II St, London.

Meetings

3-7 April, **Post-Graduate School on Aspects of Drug Toxicity**, London (R. E. Marshall, Department of Pharmaceutical Sciences, The Pharmaceutical Society of Great Britain, 1 Lambeth High Street, London SE1, UK).

10-14 April, **Symposium on HPLC with application to the Pharmaceutical and Food Industries**, Sunderland (Dr D. Dennis, School of Pharmacy, Sunderland Polytechnic, Chester Road, Tyne and Wear, UK).

12-26 April, **Chromatin Structure and Function**, Erice, Sicily (C. Nicolini, Professor of Biophysics, Temple University, 3223 North Broad Street, Philadelphia, Pennsylvania 19140).

17-20 April, **Institute of Environmental Sciences 24th Annual Technical Meeting**, Texas (B. L. Peterson, Institute of Environmental Sciences, 940 East Northwest Highway, Mount Prospect, Illinois 60056).

19-21 April, **The Origin of Major Invertebrate Groups**, Hull (Dr M. D. Brasier, Department of Geology, The University Hull, UK).

20-26 April, **Remote Sensing of the Environment**, Manila (U-M Extension Service, Conferences and Institutes, 412 Maynard Street, Ann Arbor, Michigan 48109).

25 April, **Fundamental Studies in Keratinisation**, Amsterdam (Professor M. W. Greaves, Institute of Dermatology, Homerton Grove, London E9, UK).

25-26 April, **Some Recent Results in X-ray Astronomy**, London (The Executive Secretary, attn PW, The Royal Society, 6 Carlton House Terrace, London SW1, UK).

6-11 May, **80th Annual Meeting of the American Ceramic Society**, Detroit (The American Ceramic Society Inc., 65 Ceramic Drive, Columbus, Ohio 43214).

9 May, **International Symposium on Crop Protection**, Belgium (Faculteit van de Landbouwwetenschappen, Coupure links 533, B-9000 Ghent, België).

10-12 May, **Biotechnology in Energy Production and Conservation**, Tennessee (Charles D. Scott, Oak Ridge National Laboratory, P.O. Box X, Oak Ridge, Tennessee 37830).

15-17 May, **9th International Symposium on Chromatography and Electrophoresis**, Lake Garda (Dr Alberto Frigerio, Istituto di Ricerche Farmacologiche "Mario Negri", Via Eritrea 62, 20157 Milan, Italy).

15-19 May, **3rd International Conference on Basement Tectonics**, Colorado (Dr Donald L. Baars, Department of Geology, Fort Lewis College, Durango, Colorado 81301).

15-19 May, **1st Australasian Mathematical Convention**, Christchurch (The Convention Secretary, Mathematics Department, University of Canterbury, Christchurch, New Zealand).

newly on the market

Widefield photomicroscope system. Reichert-Jung. The Reichert Polyvar has been designed for everyday research work using the high quality optics originally designed for the Univar. The objectives show faultless imaging over a field of view diameter 30. A fully automatic widefield photo system integrated into the stand permits photography for all formats equivalent to a field of view 24. The Polyvar accommodates many optical accessories as plug-in modules.

Circle No. 40 on Reader Enquiry Card

The Reichert Polyvar

Dry test meter. International Gas Apparatus. A new range of portable dry test meters designed for field or laboratory use, for testing gas unsaturated with water vapour, is announced by International Gas Apparatus of Camberley. The meters are diecast in one piece to eliminate the possibility of leaking joints and incorporate phenolic coated valve covers and a valve motion designed to eliminate the angular errors of working parts, thus reducing wear. The 6-inch dial features a large sweep hand and four totalising dials which are frictionally mounted for easy re-setting. Primary bearings, low friction seals and rugged flag rods are all designed to minimise wear and leakage. Three basic models are available, providing a range of calibrations down to 0.001 ft³, with working pressures up to 10 p.s.i. and capacities up to 325 ft³.

Circle No. 41 on Reader Enquiry Card

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Blood oxygen equilibrium analyser. TCS Medical Products Division. The Hemox analyser provides an accurate and repeatable blood oxygen association or dissociation curve of normal, abnormal and cord blood. Less than one drop of blood and 20 min of recording time are required to obtain a complete oxygen equilibrium curve of blood. The instrument uses dual-wavelength detection combined with a Clark type oxygen electrode measurement. The resulting output signals are plotted on an x-y recorder.

Circle No. 42 on Reader Enquiry Card

Ultraviolet lamp. Gallenkamp. The Gallenkamp hand-held ultraviolet lamp for chromatography is supplied with a stand under which TLC plates may be located during examination. The lamp emits ultraviolet radiation at 366 and 254 nm. It contains two long-wavelength discharge tubes with integral filters, and one short-wavelength tube with an external filter. A three-position switch selects the required wavelength or 'off'.

Circle No. 43 on Reader Enquiry Card

Liquid/gel permeation chromatograph. Waters Associates. The Waters Model 150C (150 °C) high-speed, controlled-temperature liquid chromatograph/gel permeation chromatograph provides the ability to analyse materials that dissolve only at elevated temperatures or require higher temperatures to reduce viscosity. This instrument provides rapid results, with 7–10 min separations; it is microprocessor-controlled and may be Factory or Operator Programmed.

Circle No. 44 on Reader Enquiry Card

Fast clinical analyser. Vitatron. The PA800, a high throughput analyser capable of performing 180 end point and 120 kinetics per hour, but it also lends itself to performing several assays on small batches of tests without any downtime between tests. Reagents as well as specimen are sampled, and no traditional priming of tubing with reagent is required. The analyser is programmed for each analysis by a magnetic card system which allows the operator to use ready programmed cards for common analyses or to run his own programs for other tests.

Circle No. 45 on Reader Enquiry Card

Dewpoint sensor. Cosa Corporation. Automatic calibration in the field and high sensitivity are features of the colour-coded Shaw Red Spot dewpoint sensor. The sensor covers the range of dewpoints from -80 to -20 °C, measuring moisture in gases or air to an accuracy of ±3 °C. Linearity is repeatable. Red Spot sensors use meter scales reading directly in Celsius dewpoint and equivalent p.p.m. by volume at atmospheric pressure. The Red Spot sensor features automatic calibration. Room-air moisture levels are used to calibrate the sensor.

Circle No. 46 on Reader Enquiry Card

Acoustic power measuring device. B & K Laboratories. The Type 4205 sound power source consists of two units, the generator, containing all the controls, filters, battery pack, amplifiers and meter, and the sound source, comprising two loudspeakers, associated crossover networks and so on. This combination can be used to produce continuously variable and calibrated acoustic power output up to 100 dB re 1 pW in all directions. Output can be wide band (100–10,000 Hz) or octave band pass filtered. The output can be switched off in less than 30 ms.

Circle No. 47 on Reader Enquiry Card

Red cell warmer/dry thaw unit. Forma Scientific. The Forma Scientific red cell warmer/dry thaw unit is designed for the safe warming of packed red cells from the frozen state, or warming red cells before glycerolisation and frozen storage. The Model 3614 eliminates the need for a water bath for these red cell treatment procedures and haemolysis ratings are equal to or better than those of water baths.

Forma red cell warmer

Announcing a major new journal

Immunopharmacology

Editor-in-chief: Jack R. Battisto, Cleveland Clinic Foundation, Ohio, U.S.A.

Combining the fields of immunology and pharmacology, this journal will provide a medium for the publication of full-length articles and short communications in the following areas:

- hormones and cell factors that are bioregulatory for lymphoid cell maturation, differentiation and replication.
- cellular components that assist in regulating the functioning of cells synthesizing antibodies, cells mediating cellular killing and cells controlling immunological unresponsiveness.
- mediators of immediate and delayed-type hypersensitivities.
- chemical substances that suppress as well as compounds that enhance immunological functions.
- items released through immunological and closely related pathways that are pharmacologically active at non-immunological levels.
- factors useful for prevention, prediction and diagnosis of clinical entities such as carcinomas, autoimmune diseases and immunological deficiencies.
- viral and gene products operative in immunopathology.

Immunopharmacology will constitute a much needed source for clinicians, immunologists and pharmacologists working in the fields of cancer research, autoimmunity and immunological deficiency diseases.

APPOINTMENTS VACANT

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

Physiologists with a Ph.D. and/or M.D. and postdoctoral training are invited to apply for a faculty position in Physiology, in the Faculty of Medicine, Memorial University of Newfoundland. The position is envisaged to be at the Associate level, although the rank is open to negotiation. The duties include contributing to the teaching of physiology in an integrated medical curriculum as well as some physiology teaching to nursing and science students. The successful candidate should preferably have experience in teaching human and whole animal orientated mammalian physiology and would be expected to have or develop a research program. A strong background in cardiovascular/respiratory and/or renal/body fluids physiology would fit in well with our program. The Faculty of Medicine has recently expanded its facilities into a new Health Science Center which is a part of the Memorial University Campus and will shortly also include the St John's General Hospital. The salary will be commensurate with experience and qualifications and the position is available immediately or by negotiation. Applications, including curriculum vitae and the names and addresses of three references, should be sent to: Dr C. R. Triggie, Chairman Physiology Search Committee, Faculty of Medicine, Memorial University, St John's, Newfoundland, Canada A1C 5S1. The application deadline is April 15, 1978. 1145(A)

HEAD

DEPARTMENT OF GEOLOGY UNIVERSITY OF ILLINOIS at URBANA-CHAMPAIGN

The Department of Geology of the University of Illinois at Urbana-Champaign invites applications for the position of Head of the Department of Geology. Candidates should have the Ph.D. and a demonstrable record of excellence in research and professional leadership in the geological sciences.

The Geology Department currently has 19 full-time faculty members and grants degrees at the Bachelor's, Master's and Doctoral levels. The Head is responsible for maintaining a high standard of quality in both teaching and research within the Department.

Appointment will normally be made at the rank of Full Professor; salary is open. For equal consideration, applications should be received by March 1, 1978. The desired starting date is August 21, 1978. The University of Illinois is an equal opportunity/affirmative action employer. Interested persons should submit a letter of application, vitae and names of references to the Chairperson of the Search Committee:

Professor Charles Wert
Head, Department of Metallurgy
and Mining Eng.
201 Metallurgy and
Mining Building
University of Illinois at
Urbana-Champaign
Urbana, Illinois 61801
(217)333 1440

1080(A)

UNIVERSITY OF ALBERTA

The Department of Geology, University of Alberta, Edmonton, Alberta, Canada T6G 2E3 invites applications for a full-time continuing faculty position in the field of clay mineralogy from July 1, 1978 or as soon as possible thereafter. The preferred applicant should have a mineralogical background and be prepared to apply his researches to local sedimentological problems, and/or the industrial uses of clays. The appointment will be at the Assistant Professor level (current salary level \$17,625 to \$22,888 plus health, pension and insurance fringe benefits).

Applications, with names of three referees, should be sent to the Chairman of the Department, from whom further details may be obtained. Closing date May 31, 1978. 1235(A)

ACQUISITION EDITOR

Elsevier Scientific Publishing Company, Amsterdam, The Netherlands, invites applications for the position of Acquisition Editor for the sections Earth-Sciences and Technology. After a training period, the successful candidate will, together with the section heads, further develop the publication programmes in one or both of these sections.

Candidates are expected to hold a university degree in earth-science or engineering, to be able to communicate clearly and easily, to be willing to move to Amsterdam, and to be under 35.

Applications with full curriculum vitae and an indication of present and expected salary should be sent to the Head, Personnel Department, Elsevier Scientific Publishing Company, P.O. Box 2400, Amsterdam, The Netherlands. 1228(A)

THAMES POLYTECHNIC

School of Materials
Science and Physics

RESEARCH ASSISTANT

Research Assistant required to investigate, either the properties and preparation of (a) new inorganic luminescent materials, or (b) the properties and preparation of new photovoltaic materials. The candidate should have a good honours degree in Chemistry or Materials Science. Previous experience in the above area is not required. The successful applicant will be expected to register for a higher degree.

Salary: £2,778 to £2,940 inclusive. Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by February 14, 1978. 1241(A)

IMPORTANT INTERNATIONAL PHARMACEUTICAL GROUP

is presently offering an **EXCELLENT CAREER OPPORTUNITY**
for an individual to join his
DEPARTMENT OF CLINICAL RESEARCH as

PROJECT LEADER

**FOR THE COORDINATION OF THE ACTIVITIES IN THE CNS FIELD
AT EUROPEAN LEVEL**

Preference will be given to individuals with the following qualifications:

- M.D. degree.
- Specialisation in Psychiatry and/or Neurology.
- Previous experience (3–5 years) and demonstrated capability in the design, programming, organisation and follow up of Phase II and Phase III clinical trials with psychotropic drugs.
- Good knowledge of clinical statistics and pharmacokinetics.
- Strong personal interest for clinical research.
- Good attitude towards team work.
- Age between 30 and 40 years.
- Perfect knowledge of English language.
- Availability for frequent travels within Europe.

The applicant will be responsible to the Head of the CNS Group within the Department of Clinical Research.

An excellent salary and comprehensive benefit programme accompany this position.

The working office is Paris.

Please send curriculum vitae to Box No. 1272(A).

Head of Development

Animal Health Products

This appointment offers the opportunity to lead the evaluation and development of animal health products for a major organisation which has the financial resources and a proposed commitment to expand its business in this field. Leading a compact team and working closely with the research facility, the appointed candidate will enjoy a varied role ranging from overseas field trials to laboratory work, project budgeting and scheduling, and contact with academic institutions.

Key candidate requirements include a minimum qualification of a good honours degree and proven, current research or development experience in animal sciences, gained either in industry or an academic environment. A supervisory background and overseas field trials experience would be valued. Preferred age 28 to 35.

Salary for discussion; large company benefits; pleasant Midlands location.

Please write – in confidence – to G. E. Howard ref. U.29400.

This appointment is open to men and women.

MSL

Management Consultants

Management Selection Limited
Union Chambers,

63 Temple Row, Birmingham B2 5NS

1275(A)

Microbiologist

HALIFAX

This appointment — which lacks neither variety nor interest in an expanding area of work — will appeal to a graduate Microbiologist with several years' practical experience, now seeking wider career scope.

The person appointed will head the Microbiological Section and be responsible for the microbiological control of a wide range of products.

The company is part of the Rowntree Mackintosh Group and in Halifax our manufacturing includes 'Quality Street', 'Toffo' and 'Toffee Crisps'.

A competitive starting salary is offered; benefits are those associated with a progressive company and will include relocation help, where necessary.

Please write or telephone for an application form, to:

The Personnel Manager, Rowntree Mackintosh Limited, Albion Mills, Halifax, West Yorkshire HX3 9XT. Tel: Halifax 65761. 1306(A)

 **Rowntree Mackintosh** 

UNIVERSITY OF ZAMBIA

Applications are invited for the post of
LECTURER
IN THE

DEPARTMENT OF BIOLOGY
SCHOOL OF NATURAL SCIENCES

Applicants should have good first degree in Biological Sciences and a research degree (Ph.D. or equivalent) in the appropriate discipline. The appointee will be expected to teach and develop a programme of instruction at undergraduate levels and carry out research, participating in the general curriculum of the Department.

Salary scale: K4,248 to K6,108 (£1 sterling = £1.42.) The British Government may supplement salary in range £2,220 to £2,904 p.a. (sterling) for married appointee or £330 to £834 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; baggage allowance; superannuation and medical aid schemes; regular overseas leave.

Detailed applications (2 copies) including curriculum vitae and naming 3 referees to be sent to Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia, by February 28, 1978.

Applicants resident in U.K. should send one copy to Inter-University Council 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 1302(A)

INSTITUTE OF CANCER RESEARCH

Pollards Wood Research Station
Chalfont St. Giles, Bucks.
POSTDOCTORAL
RESEARCH FELLOWSHIP

positions, tenable for 3 years, are available at the above laboratory, for a molecular biological study of the modification and changes in expression of the mammalian genome induced by chemical carcinogens. The posts would be suitable for persons trained in chemistry or biochemistry and with some experience in DNA, m-RNA and c-DNA, hybridisation, restriction enzymes, degradation, fractionation or sequencing.

The new fellows will have the support of an active research group whose earlier findings have indicated the appropriateness of the study now to be initiated.

The salary would be according to age and experience in the range £3,355 p.a. to £5,219 p.a. plus University Superannuation.

Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Summer Place, London SW7 3NU, quoting Ref. 300/G/123. 1283(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PURE AND APPLIED ZOOLOGY

Applications are invited for the post of **EXPERIMENTAL OFFICER** to assist with research in the Department of Pure and Applied Zoology at the University's Field Station. Candidates should have a degree in agricultural science or biological science, and must be prepared to look after animals as well as carry out physiological and ecological work.

The appointment is available immediately for a period up to July 31, 1979. Salary will be on the IB Scale for Other Related Staff (£2,904 to £4,811) (under review).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 56/3/D. Closing date for applications February 17, 1978. 1267(A)

THE UNIVERSITY OF
MANCHESTER
RESEARCH ASSOCIATE IN
GERIATRIC MEDICINE

Applications are invited for this post, tenable until November 1979, in the University Department of Geriatric Medicine at Withington Hospital within the Geigy Unit for Research in Aging. The work of this Unit is to carry out research into the biology of the aging process. A postdoctoral biochemist, preferably with experience in protein or connective tissue biochemistry, is required to carry out a project concerned with age-related changes in the composition of the specialised connective tissues, basement membranes. Salary up to £3,975 p.a. Applications including curriculum vitae and the names of two referees should be sent as soon as possible to Dr J. D. Schofield, Geigy Unit, Department of Geriatric Medicine, University Hospital of South Manchester, Manchester M20 8LR.

1131(A)

THE AUSTRALIAN
NATIONAL UNIVERSITY
COMPUTER SERVICES CENTRE
DIRECTOR

The A.N.U. invites applications for the position of Director of the Computer Services Centre. The Centre was established in 1977 following a re-organisation to provide computing and related facilities for both academic and administrative purposes.

In carrying out the work of the Computer Services Centre, the Director will work with a Management Committee for the Centre and will be a member of the committee which deals with University computing policies. In all other respects he will be responsible directly to the Vice-Chancellor.

The Computer Services Centre is equipped with a 2 x 1 Univac 1100/42 which provides remote terminal and batch facilities. Other terminals and peripheral equipment communicate with the central machine through a PDP 11/45. There is also an IBM 360/50 Model H which handles administrative data processing and 11/40 used for development work.

The Director will be responsible for the development of Computer Service and network facilities. On current budget provisions the Centre has a staff of more than 30 personnel organised into programming, operations, technical and director's support teams.

The University is seeking an experienced senior person with professional and tertiary qualifications. Applicants should have management experience in a large organisation and skills in both hardware and software systems. Importance will be attached to capacity to supervise the operation of a centre which is required to provide large scale scientific batch processing and an efficient interactive system involving remote sites.

The Director will be expected to take a prominent part in the formulation of plans for the development of computing services throughout the University. He will be expected to have sufficient experience to negotiate on behalf of the University with computer suppliers and to administer contracts.

A salary of the order of \$A24,000 to \$A26,000 per annum is contemplated.

Reasonable travel and removal expenses will be paid and assistance with accommodation will be provided to the successful applicant if appointed from outside Canberra.

Further information about the position and the Computer Services Centre will be supplied on request to the Registrar, Australian National University, P.O. Box 4, Canberra, A.C.T. 2600 Australia, quoting reference number 78016. The successful applicant will be required to undergo a medical examination. Written applications, quoting reference number 78016, should be forwarded to the Registrar at the above address with whom applications close on **February 28, 1978.**

Research Biologist (Agrochemicals)

May & Baker Ltd., is an international Company manufacturing and marketing a wide range of pharmaceutical, agrochemical and fine chemical products.

A vacancy has arisen in the Bioavailability Research Section at the Company's Research Station at Ongar, Essex, for a biologist to study the effects of physicochemical and environmental factors on the activity of new herbicides, fungicides and plant growth regulators. The work involves laboratory experiments with whole plants grown in controlled conditions, and affords opportunities for teamwork with chemists, and with other biologists including field trials officers.

Applicants should be aged between 23 and 28 years with a first or second class honours degree in botany, plant physiology or plant pathology. Some post-graduate experience with relevant laboratory techniques would be useful.

Conditions of employment include flexible working hours, subsidised meals and a contributory pension scheme with life assurance.

Please telephone 01-592 3060 extension 2506 for an application form or write to

M&B May & Baker

Miss P. Loveday,
Personnel Officer,
(Scientific Staff),
May & Baker Ltd.,
Dagenham, Essex RM10 7XS
quoting reference

1296(A)

UNIVERSITY OF LONDON
INSTITUTE OF
NEUROLOGY
RESEARCH TECHNICIAN

to observe animal behaviour and/or to do biochemical work. Some general duties. Salary £1,824 to £2,910 (plus £450 London Weighting). Curriculum vitae and names of two referees to Professor G. Curzon, Institute of Neurology Labs., 33 Johns Mews, London WC1N 2NS.

1304(A)

UNIVERSITY OF SYDNEY
Australia
PROFESSIONAL OFFICER
SCHOOL OF CHEMISTRY
(Theoretical) (Spectroscopy)

Applications are invited from appropriately qualified persons. Possession of a Ph.D. or equivalent qualification in Physics or Chemistry will be highly regarded. The appointment is initially until December 31, 1978, with good prospects of renewal. Commencing salary in range \$A10,264 to \$A15,703 per annum.

Wide experience in experimental spectroscopy (U.V./visible/I.R.), preferably including laser operation, is essential. The person appointed will take overall responsibility for maintaining and operating existing spectroscopic equipment, and will be expected to be capable of designing further instrumentation. Appointee will be encouraged to participate in the research work of the Department in this area, which is at present concerned primarily with solid-state spectroscopy of mixed-valence systems.

Applications, including details of qualifications and names of two referees, should be sent to the Registrar, University of Sydney, N.S.W., 2006, Australia. Further information may be obtained from Professor N. S. Hush, School of Chemistry in the University.

1279(A)

EXPERIENCED
TRANSLATORS

for English translations of Soviet scientific research journals in chemistry, physics, geology, meteorology, engineering, life sciences and other scientific subjects. English as native language preferred. Send résumé to Box 1260(A).

BAYERO UNIVERSITY
NIGERIA

Applications are invited for the post of PROFESSOR in the DEPARTMENT OF MATHEMATICS.

Applicants should possess a doctorate and have substantial record of published research, together with considerable experience of University teaching at undergraduate and post-graduate levels, including supervision of research programmes. Substantial administrative experience will also be expected and applicants with interests in any branch of Mathematics will be considered. Special consideration will be given to the areas of analysis, algebra and statistics.

Salary scale: N11,268 to N12,420 p.a. (£9,549 to £10,525 p.a. sterling) (£1 sterling=N1.18). There may be supplementation of salary for married appointee of £2,160 p.a. (sterling) (reviewed annually and normally free of all tax) and provision of children's education allowances and holiday visit passages. Single appointee will not attract the supplement. 25% of salary contract addition (partly taxable) is also payable. Family passages; various allowances; superannuation scheme; biennial overseas leave.

Detailed applications (2 copies) including a curriculum vitae and naming 3 referees to be sent by February 28, 1978 to Registrar, Bayero University, PMB 3011, Kano, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

1255(A)

San Diego State University announces the establishment of the E.F.F. Copp Chair of Biochemistry. The Search Committee seeks an outstanding scientist whose research interests lie in the areas of diabetes and carbohydrate metabolism with special emphasis on hormone receptors, cell membranes or mechanism of hormone action. Salary is highly competitive and negotiable. Applications should be submitted with curriculum vitae by April 1, 1978 to: Copp Chair Search Committee, Department of Chemistry, San Diego State University, San Diego, CA 92182. An Affirmative Action/Equal Opportunity/Title IX Employer. 1225(A)

UNIVERSITY OF
STRATHCLYDE
PROFESSOR OF
BIOCHEMISTRY

Applications are invited for appointment as Professor and Head of Department of Biochemistry in the School of Biological Sciences following the appointment of Professor P. J. Heald as Dean of the Faculty of Science at the Memorial University, Newfoundland.

Application forms and further particulars (quoting 3/78) may be obtained from the Registrar, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by February 28, 1978.

1292(A)

Senior Scientific Officer/ Higher Scientific Officer

£3,254 — £5,778 (plus supplements)

Applications are invited for a pensionable post in the Animal and Crop Husbandry Research Division of the Department of Agriculture located at Hillsborough, Co. Down.

The duties will include investigations into the feeding and management of beef cattle. The successful candidate may also be required to undertake teaching duties in the Faculty of Agriculture and Food Science, Queen's University, Belfast.

Appointment may be at Senior Scientific Officer or Higher Scientific Officer level.

SENIOR SCIENTIFIC OFFICER

Applicants must be over 25 and under 32 years of age on 31 December 1978 and possess a First or Second Class Honours Degree in Agriculture and at least 4 years' appropriate post-graduate experience.

HIGHER SCIENTIFIC OFFICER

Applicants must be under 30 years of age on 31 December 1978 and possess an Honours degree as above and at least 2 years' appropriate post-graduate experience.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

SALARY SCALES

Senior Scientific Officer—£4,185—£5,778

Higher Scientific Officer—£3,254—£4,454

In addition to the salary scales quoted pay supplements of between £310.59 and £522.00 per annum will be payable.

Grading and starting salary will be related to qualifications and experience.

Please write or telephone for an application quoting job reference SB 41/78/NA, to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 255). Completed forms must be returned to arrive not later than 16th February 1978, 1226(A).

**NORTHERN IRELAND
CIVIL SERVICE**

BIOCHEMISTRY FACULTY POSITION

The Biochemistry Department, University of California, Riverside, invites applications for an Assistant Professor position (tenure track) effective Summer, 1978. Although we have a slight preference for a person with a strong background in physical biochemistry who will initiate research into the structure and function of biologically interesting macromolecules and/or biological membranes, applications from outstanding individuals in other areas of biochemistry will receive serious consideration. The successful candidate will participate in the department's instructional program at the undergraduate and graduate level. Candidates should include in their application a statement of their current and future research objectives and a statement of their teaching experience and areas of competence. Send curriculum vitae, complete bibliography, duplicate copies of three representative publications, and the names and addresses of three references to: BIOCHEMISTRY SEARCH COMMITTEE, Department of Biochemistry, University of California, Riverside, CA 92521. Applications will be accepted until March 10, 1978 or until a suitable candidate is located. The University of California is an Equal Opportunity/Affirmative Action Employer. Minority and women candidates are encouraged to apply. 968(A)

UNIVERSITY HOSPITAL OF SOUTH MANCHESTER

Two research technician positions are available in the laboratories of the University Department of Geriatric Medicine at Withington Hospital within the Geigy Unit for Research in Aging. The work of this Unit is to carry out research into the biology of the aging process and the work on which the appointees will be engaged is concerned with biochemical aspects of this problem.

One person will be required to work with a Postdoctoral Research Assistant and the other to work on other biochemical aspects of aging. Applicants should have O.N.C. or equivalent in biochemistry or a related subject and several years' relevant experience. One post is financed by a M.R.C. grant which terminates at the end of 1979. The other post is supported by Geigy Unit funds and this appointment will be for one year initially, renewable for a further one or two years. Salary up to £2,835 per annum on the Grade 3 technician scale.

Applications including curriculum vitae and the names of two referees should be sent as soon as possible to Dr J. D. Schofield, Geigy Unit, Department of Geriatric Medicine, University Hospital of South Manchester, Nell Lane, Manchester M20 8LR. 1259(A)

**PLYMOUTH
POLYTECHNIC**

Technical Services

RESEARCH TECHNICIAN (MICROBIOLOGY/ BIOCHEMISTRY)

Salary: £2,529 to £2,853
(plus supplement range:
£454.08 to £470.28)

To join research group investigating pathogenicity of bacteria in fish. The successful applicant will work on the purification and mode of action of bacterial toxins.

Applicants should possess H.N.C. or degree in microbiology, biochemistry or related subjects. The project is supported by an S.R.C. grant and is therefore tenable for 15 months in the first instance.

Application forms, to be returned by February 17, 1978, can be obtained with further particulars from the Personnel Officer. 1294(A)

PLYMOUTH POLYTECHNIC DRAKE CIRCUS
PLYMOUTH PL4 8AA

UNIVERSITY OF MELBOURNE

NEW DEVELOPMENT PROGRAMME IN ANTARCTIC STUDIES AND RESOURCES

This new programme is being established as an inter-faculty initiative of which the first phase supports two limited tenure lectureships in the Faculty of Science.

LECTURESHIP (Limited Tenure) in ANTARCTIC GEOPHYSICS DEPARTMENT OF GEOLOGY

Applications are invited for a geophysicist to establish a research and teaching programme concerned with the structure of the Antarctic continent, its continental shelf and its relation to the Southern Ocean and the Australian Plate. Preference will be given to applicants capable of mounting a marine geophysical programme of the Antarctic continental shelf, but others with specific geophysical programmes which could be mounted on the Antarctic continent will also be given full consideration.

LECTURESHIP (Limited Tenure) in BOTANY DEPARTMENT OF BOTANY

A lecturer is required to develop a research programme in some aspects of Antarctic Botany involving, for preference, one or another of the following general areas: marine phytoplankton; marine benthic flora; ecology of terrestrial bryophytes and lichen communities; terrestrial phycology. The appointee will also be required to participate in the teaching of appropriate units at undergraduate and post-graduate levels. Preference will be given to applicants with a Ph.D. or equivalent research degree and post-doctoral research experience.

Both positions will be available for 3 years from date of appointment. SALARY: \$A14,851 to \$A19,551 per annum.

Further information, including details of application procedure, is available from The Registrar, or from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. Applications should be addressed to The Registrar, University of Melbourne, Parkville, Victoria, 3052, Australia. Applications close on March 15, 1978. 1276(A)

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOLOGICAL SCIENCES

LECTURESHIP

Applications are invited for a Lectureship in the above department from persons with an interest in any field of Plant Biology other than nitrogen metabolism and photosynthetic prokaryotes.

Salary on the scale £3,333 to £6,655 (currently under review) with initial placing dependent on qualifications and experience. Superannuation under U.S.S. Grant towards removal expenses to Dundee.

Applications (6 copies; overseas applicants 1 copy) quoting Reference EST/17/78J and naming three referees should be lodged by February 23, 1978 with The Secretary, The University, Dundee DD1 4HN, from whom further particulars may be obtained. 1188(A)

PORTSMOUTH POLYTECHNIC

RESEARCH FELLOW

A postdoctoral research fellow (S.R.C.) (Male or Female) is required to work on the higher-order structures of Chromatin at a time when studies of the structure of the chromosome are at a rapid stage of development.

The post is in Dr E. M. Bradbury's group and it is expected that a wide range of physical and biochemical techniques will be used including X-ray and Neutron scattering. The successful candidate would probably be an experienced physical Biochemist or a Physicist or Chemist keenly interested in biological problems.

The appointment will be for three years.

Salary: £3,849 to £4,059.

Application forms and further particulars are available from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ to whom completed applications should be returned by: February 21, 1978. Please quote ref. S44. 1293(A)

UNIVERSITY OF LONDON KING'S COLLEGE

LECTURESHIP IN ANATOMY

Applications are invited for a Lectureship in Anatomy. Preference will be given to candidates interested in teaching Embryology who propose to continue an active programme of research in Development. Applicants should be prepared to assist in the teaching of Topographical Anatomy.

Salary scale £3,355 to £6,655 per annum plus £450 per annum London Allowance. Universities Superannuation Scheme contributions would be payable.

LECTURER/ DEMONSTRATOR IN ANATOMY

A vacancy exists for a full-time Demonstrator in Topographical Anatomy. The post is tenable for twelve months and is suitable for applicants preparing for the Primary F.R.C.S. examination.

Salary scale £3,355 to £6,655 per annum plus £450 per annum London Allowance. Universities Superannuation Scheme contributions would be payable.

Application forms and further particulars for the above posts may be obtained from the Registrar, King's College, Strand, London WC2R 2LS, to whom applications together with the names of two referees should be sent to reach him by Friday, February 24, 1978 quoting reference 191601/N. 1254(A)

BACTERIOLOGIST HEAD OF LABORATORY

An opportunity exists to join a team of microbiologists engaged in chemotherapeutic evaluation of new drugs.

We seek an applicant with experience in bacteriology and perhaps in chemotherapy. Preferred age 28–35 years. His (her) main responsibilities will be the development of new model infections, as well as the performance of efficacy and pharmacokinetic studies.

Our research is founded on an interdisciplinary approach, and successful applicants would have the opportunity to pursue basic research projects in well established research groups studying a wide range of biological problems.

We can offer excellent working conditions in well equipped laboratories. An attractive salary will be paid, and travel expenses from country of origin will be refunded.

Interested scientists are invited to send applications stating age, citizenship, qualifications and experience to Forschungsinstitut, A-1235 Wien, Brunner Strasse 59, Austria. 1307(A)

Senior Research Pharmacologist

A vacancy has arisen at our Welwyn Garden City site for a Senior Research Pharmacologist in the Pharmacology Department.

The Department comprises three sections, cardiovascular, anti-inflammatory and general pharmacology. The successful applicant, male or female, will be required to lead a small project team and contribute to the overall Research effort in the general pharmacology section.

Applications are invited from those with 2 to 3 years' post-doctoral experience who can demonstrate achievements in innovative research.

We offer excellent working conditions in modern and well-equipped laboratories. The salary will be commensurate with experience, additional benefits and facilities include a Christmas Award, contributory pension scheme, free BUPA membership, a subsidised restaurant and, in appropriate cases, assistance towards relocation expenses.

For further information and an application form, please contact the Research Personnel Department (quoting reference RD4) Roche Products Limited, PO Box No 8, Welwyn Garden City, Hertfordshire AL7 3AY, telephone Welwyn Garden 28128. The closing date for applications is 23 February 1978.

1158(A)

ROCHE

IMPERIAL COLLEGE LECTURESHIP IN PLANT PATHOLOGY

Applications are invited for this appointment from Plant Pathologists with special interests in the physiological aspects of diseases caused by micro-organisms. Starting salary up to £5,219 p.a. in the range £3,761 to £6,655 p.a. (under review), according to experience, plus £450 London allowance.

Applications, giving details of experience and the names of two referees, should be sent by March 13, 1978 to Professor R. K. S. Wood, F.R.S., Imperial College, London SW7, from whom further particulars about the appointment may be obtained. 1231(A)

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH DIVISION OF VIROLOGY

A scientific staff vacancy will occur in the autumn in a team investigating the fundamental aspects of virus infection using the adenovirus model. The post would be suitable for a researcher with postdoctoral experience in biochemical and/or virological techniques and would be of three years duration with an annual salary, depending on experience, in the range £3,535 to £5,669 p.a. including London Allowance. Superannuation provision.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before February 28 1978. 1243(A)

HOSPITAL FOR TROPICAL DISEASES

4 St Pancras Way, London NW1 2PE

LABORATORY TECHNICIAN

required in the Clinical Nutrition and Metabolism Unit at this Hospital to assist in research on the nutritional effect of surgical trauma and infection. The post would suit state registered persons or others studying for H.N.C. &c. in Biochemistry or Microbiology.

Applications in writing, giving full career details and naming two referees, should be sent to Dr A. M. Tomkins at the Hospital, from whom further particulars are available. 1233(A)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF SURGERY

Head of Department:

Professor G. D. Chisholm

LECTURER—NON-MEDICAL

Applications are invited for the above post which is now vacant. Applicants should be Steroid Biochemists, preferably Ph.D. graduates, with experience in research in reproductive endocrinology. The main research projects are related to hormone measurement and receptor assays in prostatic disease. The salary will be at an appropriate point on the scale £3,333 to £6,655 per annum.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL, with whom applications (six copies) including curriculum vitae and the names and addresses of two referees, should be lodged not later than February 25, 1978. Please quote Reference 1006. 1270(A)

UNIVERSITY OF IDAHO

Assistant or Associate Professor/Ornamental Horticulturist. University of Idaho. Responsibilities: approximately 80% teaching, 20% research. Ph.D. required. Position available after July 1, 1978. Position open until acceptable candidate is selected. Inquiries should be sent to: Ornamental Horticulture Position, Dept. of Plant & Soil Sciences, University of Idaho, Moscow, Idaho 83843. (Ph. 208/885-6276. A.A./E.O. employer and educational institution. 1148(A)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF AGRICULTURE
AND HORTICULTURE

Applications are invited for the post of
RESEARCH ASSISTANT

to work on seed production in amenity grasses at the University of Nottingham School of Agriculture, Sutton Bonington under the direction of Dr P. D. Hebblethwaite, director of the herbage seed research programme.

The project will be financed by Mommersteeg International and will be for a period of three years from October 1, 1978. The successful applicant will be expected to register for a higher degree and should have an honours degree, Upper Second Class or First Class, in either Agriculture, Horticultural Botany, Plant Science or Horticulture. Remuneration will be linked to M.A.F.F. Studentship Maintenance Grants—at present £1,475 per annum.

Applications including a curriculum vitae and the names and addresses of two referees should be sent to A. Whitting, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough, as soon as possible. 1262(A)

THE OPEN UNIVERSITY

Staff Tutor in Biology

NORTHERN REGION

(based in Newcastle upon Tyne)

Applications are invited for a full-time post of Staff Tutor in Biology tenable from 1 April, 1978 or as soon as possible thereafter. The Staff Tutor will be appointed to the Faculty of Science and will be based in the University's Northern Regional Office. The main duties of the Staff Tutor will include liaison with members of the University's central academic staff at Walton Hall and assisting the Regional Director, Northern Region (to whom the Staff Tutor is organisationally responsible), in e.g., the appointment, supervision and training of local part-time tutors. Applications from those with interests in any field of biology are invited but will be particularly welcome from those with interests in neurobiology; mammalian physiology; genetics. Commencing salary will be within the lower part (£3,333 to £4,190) of the Lecturers scale £3,333 to £6,655 per annum, with USS benefits.

Details and application forms are available from The Personnel Manager (STB2), The Open University, P.O. Box No. 75, Walton Hall, Milton Keynes MK7 6AL. Tel. Milton Keynes 63868/9. Closing date for applications 17 February, 1978. 1267(A)

Un laboratoire pharmaceutique
de réputation internationale, désireux de
développer son potentiel de Recherche, engage un

Directeur des Recherches Chimiques et Pharmacologiques

Sous l'autorité du Directeur de la Recherche, il se verra confier la direction et l'animation de notre Centre de Recherches.

Il sera chargé de la coordination entre les chercheurs et le siège, ce qui l'amènera à participer à la définition des orientations de recherche.

jeune Médecin ou Pharmacien

il s'imposera tant par son niveau de compétence scientifique, que par son sens du dialogue et de la communication.

en indiquant la réf. PH sur l'enveloppe.

1224(A)

DEPARTMENT OF METALLURGY AND SCIENCE OF MATERIALS UNIVERSITY OF OXFORD RESEARCH FELLOWS

The Hydration and Development of Strength of Cement

Two posts are available to take part in a project involving research into hydration mechanisms in Portland cement, the effect of modifying additives and the relationship between microstructure and strength. This is an area of Materials Science which would appeal to a person interested in working in an interdisciplinary field involving one or more of the following: electron microscopy, aspects of silicate and colloid chemistry, mechanical property fracture studies.

One post is supported by the S.R.C. and the other by I.C.I. Mond Division and both are tenable for a period of three years. Candidates should possess a Ph.D. degree or equivalent. Salary in the range £3,333 to £5,627 (under review). Applications including a brief curriculum vitae and names and addresses of two referees should be sent to the Administrator, Department of Metallurgy and Science of Materials, Parks Road, Oxford OX1 3PH.

1236(A)

NATURAL ENVIRONMENT RESEARCH COUNCIL INSTITUTE OF GEOLOGICAL SCIENCES GEOPHYSICAL ELECTRONICS TECHNICIANS

The Institute has a vacancy for an Electronics Technician graded Professional and Technology Officer IV in the Applied Geophysics Unit, at BASHLEY ROAD, LONDON NW10. Applicants should know the principles of electronics and have practical experience of electronic instrumentation, together with a familiarity of associated electromechanical devices. A working knowledge of mechanical workshop practice and an ability to use hand tools is desirable. Duties are the inspection, testing, maintenance and repair of an extensive range of geophysical instruments, both in the workshop and the field.

QUALIFICATIONS

- ONC in electrical or electronic engineering or
- an equivalent or higher qualification acceptable to NERC.

All candidates must have served an apprenticeship, or have had equivalent training; in addition they will normally be expected to have at least 3 years' experience. Exceptionally, this latter condition may be waived for candidates with ONC who have completed a 4-year period of apprenticeship or training.

SALARY

£2,425 per annum at age 21, £2,970 at age 27 rising to a maximum of £3,450.

The post attracts Outer London Weighting of £275 per annum. In addition there are supplements to salary of £313.20 per annum and 5% of total earnings, subject to a minimum of £130.50 and a maximum of £208.80 per annum.

ANNUAL LEAVE

20 days per annum, plus 9½ days public and privilege holidays.

Application forms can be obtained from Recruitment Section, Institute of Geological Sciences, Exhibition Road, London SW7 2DE.

Closing date for receipt of completed application forms is 24 February 1978.

Please quote reference PTO/AGU/78/1.

1305(A)

UNIVERSITY OF READING LECTURERSHIP IN SOIL SCIENCE

Applications are invited for a Lecturership in Soil Science.

The person to be appointed will be concerned with teaching and research in the fields of pedology and soil survey, and may be required to take field courses in term and vacation periods. It is hoped to appoint a person with field experience of soil survey work.

The person appointed should take up duties as soon as possible.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than March 31, 1978.

1266(A)

THE CHINESE UNIVERSITY OF HONG KONG

invites applications for the post of Technician (with prospects of promotion to Senior Technician) in Electron Microscopy in the Department of Biology. Requirement: a university degree or a diploma/certificate from a polytechnic in biology with experience in Electron Microscopy. Preference will be given to candidates with a strong electronics background.

Salary range: £2,700 to £4,860 p.a. approx. for technician; £5,100 to £5,860 p.a. approx. for senior technician depending on qualifications and experience. Also superannuation (15% University, 5% employee), medical benefits, annual and sick leave. Appointee is expected to assume duty on June 1, 1978.

Further information and application forms are obtainable from the Personnel Section, C.U.H.K., Shatin, N.T., Hong Kong. Applications, marked "APPLICATION" on cover, should be returned before March 15, 1978.

1237(A)

COMMONWEALTH AGRICULTURAL BUREAUX Vacancy for SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH FORESTRY BUREAU Commonwealth Forestry Institute

South Parks Road,
Oxford OX1 3RD

Duties of post: The scrutiny of technical literature, selection and preparation of abstracts in many subjects related to forestry or forest products (this may involve visits to outside libraries), indexing, preparing for the press and dealing with technical enquiries.

Flexible working hours are based on 37 hours per week. Applicants wishing to work 18½ hours per week, with appropriate adjustments of salary, etc., will be considered.

Qualifications: Applicants should be graduates in forestry or in a biological science or in a relevant branch of physical or engineering science. A good reading knowledge of a modern language, preferably Russian, German, French or Spanish, is required.

Salary: In the scales £2,149 to £3,527 to £4,454 plus cost-of-living supplement and a compensatory allowance (taxable but not superannuable) of 41% to offset personal contribution to F.S.S.U. Starting salary according to qualifications, experience and age. Promotion to higher scales on merit.

Application forms and full particulars from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: February 27, 1978.

1251(A)

TECHNICIAN required in Department of Chemical Pathology for general day to day duties required for running of a section of the Department and to assist with research project involving bacterial cultures and enzyme assays. Salary according to experience and qualifications within scale £2,982/4,259 p.a. plus £354 p.a. London Allowance. Apply with full details and names of two referees to, The Secretary, St Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref. T/CP/N.

1253(A)

UNIVERSITY OF OXFORD AGRICULTURAL RESEARCH COUNCIL

Unit of Muscle Mechanisms and

Insect Physiology

DEPARTMENT OF ZOOLOGY RESEARCH ASSISTANT

Applications are invited for a post, financed by the Muscular Dystrophy Association of America, to work on the composition and structure of muscle Z discs. Experience in protein biochemistry and/or electron microscopy essential. Candidates should have a good first degree; the post would also be suitable for a postdoctoral worker. The vacancy is available immediately and is for one year with the possibility of renewal. Salary scale Research Support 1B (£2,904 to £4,811 p.a.) or 1A (£3,333 to £5,627 p.a.) with U.S.S. benefits.

Applications with Curriculum vitae and names of two referees to Professor J. W. S. Pringle, A.R.C., Unit, Department of Zoology, South Parks Road, Oxford, before February 20,

1288(A)

FACULTY POSITION— PLANT BIOCHEMIST

Applications are requested for an appointment as ASSISTANT PROFESSOR OF BIOCHEMISTRY in the tenure track at the University of California, Riverside, effective Summer 1978. Applicants should have demonstrated ability in research in plant biochemistry and the capability to develop a vigorous research program in this area. This individual will be expected to teach a course in plant biochemistry at the upper division/graduate level and participate in other teaching activities of the department. Candidates should send curriculum vitae, a statement of their current and future research interests and ask three scientists familiar with their work to send us letters of recommendation. Applications will be accepted until March 10, 1978 or until a suitable candidate is located. Address correspondence to: SEARCH COMMITTEE, PLANT BIOCHEMIST, Department of Biochemistry, University of California, Riverside, CA 92521. The University of California is an Equal Opportunity/Affirmative Action Employer. Minority and women candidates are encouraged to apply.

969(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of:

LECTURER

in the above Department. The person appointed will participate in teaching biochemistry to science and to medical students. Facilities and opportunities for research are excellent. The appointment will date from October 1, 1978. Salary on the lecturer scale £3,333 to £6,655.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/10/D. Closing date for applications March 10, 1978.

1248(A)

UNIVERSITY OF
MELBOURNE
LECTURESHIP IN
SOIL SCIENCE
SCHOOL OF AGRICULTURE AND
FORESTRY

Applications are invited for the above-mentioned position, commencing October 1, 1978. The appointee will be required to lecture in the Soil Science courses given in the School of Agriculture and Forestry and to participate in the associated practical classes.

The appointee will be encouraged to develop his own research interests and to participate in postgraduate training programmes. Preference will be given to those applicants interested in biological aspects of soil science or chemical aspects of soil fertility.

QUALIFICATIONS: Ph.D. or equivalent, with some postdoctoral experience.

SALARY: \$A14,851 to \$A19,551 per annum.

Further information, including details of application procedures and conditions of appointment, is available from The Registrar, University of Melbourne, Parkville, 3052, Victoria, Australia, or from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. Applications should be addressed to The Registrar and close on March 15, 1978.

1277(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the post of
SENIOR LECTURER/
LECTURER

in the
GEOLOGY DEPARTMENT
SCHOOL OF MINES

Applicants should possess a higher degree and teaching or research experience in the following fields: Applied Geochemistry, Economic Geology and Structural Geology.

Salary scales: Senior Lecturer K6,324 to K7,200 p.a.; Lecturer K4,248 to K6,108 p.a. (£1 sterling = K1.42). A local supplement of salary is likely to be provided; this is paid by mining companies. The British Government, may supplement salaries at a level which will allow the overall income of appointees to equate with other staff members whose salaries are supplemented by the British Government. Family passages; baggage allowance; superannuation and medical aid schemes; regular overseas leave.

Detailed applications (2 copies) together with curriculum vitae and naming 3 referees to be sent to Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia, by February 28, 1978.

Applicants resident in U.K. should send one copy of application to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 1303(A)

THE HANNAH
RESEARCH INSTITUTE
SCIENTIFIC OFFICER

in the
BIOCHEMISTRY DEPARTMENT

A vacancy exists in the Biochemistry Department for a Scientific Officer to assist with work on the metabolism by rumen micro-organisms of aromatic compounds present in forage plants and the effects that these metabolic processes have on the utilisation of dietary polysaccharides. Candidates should have a degree, H.N.C. or equivalent, in Chemistry or Biochemistry.

Salary according to qualifications and experience in scale £2,592 to £4,032 including current pay supplements. Non-contributory superannuation.

Further particulars may be obtained from The Secretary, The Hannah Research Institute, Ayr KA6 5HL, to whom applications, with full curriculum vitae and the names and addresses of two referees should be sent by: February 27, 1978. 1290(A)

THAMES POLYTECHNIC
SCHOOL OF
MATERIALS SCIENCE AND
PHYSICS
X-RAY AND NUCLEAR
LABORATORY
TECHNICIAN GRADE 5

Applications are invited for a technician for the X-ray and nuclear laboratories who will be required to operate X-ray equipment, handle radioactive sources and be responsible for keeping exposure records. Candidates should have a recognised apprenticeship or H.N.D./H.N.C. qualification and at least eight years' relevant experience.

Salary scale: £3,027 to £3,483 including London weighting plus personal allowance (i.e. 5% of gross pay; min. £2.50, max. £4.00).

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by February 14, 1978. 1242(A)

THE UNIVERSITY AT
ALBANY
BEHAVIORAL ECOLOGY
FULL PROFESSOR

The Department of Biological Sciences is seeking a senior scientist of stature in the area of Behavioral Ecology for an appointment beginning fall 1978. The department is interested in applicants who currently maintain an active research program and who have demonstrated substantial scientific achievements. The appointee will be expected to provide direction and leadership for the ecology/animal behavior program which currently consists of six faculty. The department has approximately 70 graduate students in M.S. and Ph.D. programs.

Please send curriculum vitae and three references to Kenneth P. Able, Chairman of Search Committee, Department of Biological Sciences, SUNY at Albany, 1400 Washington Avenue, Albany, NY 12222.

The State University of New York at Albany is an Equal Opportunity/Affirmative Action Employer.

1263(A)

UNIVERSITY OF CRETE

The Physics Department of the University of Crete will admit its first freshman class in the 1978-79 academic year at the Sciences Campus near Knossos. During the 1978-79 year the organisation of both the undergraduate and graduate curricula will be completed and the administrative structure of the Department will be established. Faculty positions are open at all levels. Applications for visiting as well as regular appointments are solicited. The visiting appointments will be made in the Spring of 1978 and some regular ones will be made during the 1978-79 year. Send all required documents to Professor D. Katakis, 71 Solonos Street, Athens 143. Send a copy of your curriculum vitae and reference letters to Prof. G. C. Alexandrakis, Chairman, Department of Physics, University of Miami, Coral Gables, Florida 33124 (Acting Chairman, Physics Department, University of Crete). 1265(A)

PALYNOLOGIST

Applications are invited for a Post-doctoral Fellowship in palynology. The Fellow will collaborate on a project investigating Holocene environmental changes in the Lake Manitoba Basin. The appointment may be made as early as May 1978 and will be for 1-2 years, subject to funding approval. Send resume and names of three referees to Dr J. T. Teller, Department of Earth Sciences, University of Manitoba, Winnipeg, Manitoba, Canada, R2T 2N2. 1261(A)

The Daresbury Laboratory has a vacancy at Senior Scientific Officer level for a

Solid State Theoretician

The fields of interest of the Theory Group at Daresbury are solid state, atomic and molecular, and nuclear.

At the Laboratory a purpose-built X-ray and ultraviolet source and a major nuclear structure facility are under construction. An IBM 370/165 computer is installed at the Laboratory, and a computational science group has recently been established working mainly in the quantum chemistry area.

The appointment would be a permanent one at Senior Scientific Officer level made according to age and experience in the range £4,185 to £5,778. In addition there are pay supplements of (a) £312.00 per annum and (b) 5% of total salary subject to a minimum of £130.50 per annum and a maximum of £208.80 per annum. There is a non-contributory superannuation scheme and a generous leave allowance.

The successful applicant, of either sex, will be expected to take a strong interest in synchrotron radiation experiments which are being planned on the new source. Applicants should possess a Ph.D degree and several years' research experience in solid state theory.

Closing date: 1 April 1978

Please write enclosing curriculum vitae, the addresses of two referees and quoting reference number DL/611/T to:

The Personnel Officer

1227(A)

DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

UNIVERSITY OF
QUEENSLAND
DEPARTMENT OF
PHYSIOLOGY
PHYSIOLOGIST
(TECHNOLOGIST B)

A graduate is required who is experienced in or has an interest in the field of endocrinology or fetal physiology. Preference may be given to a person experienced in the development of radio immunoassays for steroid hormones or prostaglandins.

The duties would be to establish the above techniques, supervise the training of technical staff and to collaborate in the Departmental research programs in these areas.

Further information may be obtained from Professor G. D. Thorburn in the University.

Salary: \$A382.10 to \$A570.20 per fortnight.

Applications, quoting reference No. 00178 and providing the names and addresses of 2 or 3 referees, should be forwarded to the Staff Officer, University of Queensland, St Lucia, 4078, Qld. Australia. 1278(A)

UNIVERSITY COLLEGE
HOSPITAL MEDICAL
SCHOOL
TECHNICIAN

to work in the field of leukaemogenesis. Work will entail attempts to define factors leading to host resistance and mode of inheritance of leukaemia in mice, and will involve fine techniques such as surgical manipulation of early mouse embryos as well as general handling of mice. Experience in mouse handling and record keeping is essential, whilst a working knowledge of basic virological and immunological techniques would be an advantage. Although part of a small team, the successful applicant must be prepared for the responsibility of carrying out some of his or her duties alone.

Written applications in first instance to Professor D. V. I. Fairweather, (N) Department of Obstetrics and Gynaecology, University College Hospital Medical School, 88-96 Chenies Mews, London WC1E 6HX, from whom further information may be obtained. 1301(A)

QUEENSLAND AGRICULTURAL COLLEGE

A MULTI-VOCATIONAL
COLLEGE OF ADVANCED EDUCATION
LAWES (GATTON)
QUEENSLAND, AUSTRALIA

DIRECTOR

The Council of the Queensland Agricultural College invites inquiries and applications for the position of Director of the College, which will become vacant on the retirement of the present Director in November, 1978.

The College, situated 96 kilometres West of Brisbane on the Brisbane/Toowoomba Highway, is one of ten autonomous colleges of Advanced Education in Queensland. It has a current enrolment of 750 students and offers a wide range of courses in the Rural Technology, Rural Management, Food Technology, Food Service Management and Hospitality Management fields, at the degree, diploma, associate diploma and certificate levels.

The Director is Head and Principal Academic and Administrative Officer of the College. The successful applicant will be an imaginative and purposeful leader. He or she will have had extensive relevant academic, practical and administrative experience.

The salary and other conditions compare favourably with similar senior academic posts throughout Australia.

Conditions of appointment and further details of this position and of the Queensland Agricultural College are available from The Chairman of the Council Mr E. P. S. Roberts, to whom inquiries and applications should be addressed at Queensland Agricultural College, Lawes, Queensland, Australia, 4345.

Applications close on May 1, 1978.

1250(A)

**UNIVERSITY OF
WARWICK
RESEARCH TECHNICIAN
THE DEPARTMENT OF
BIOLOGICAL SCIENCES**

has a vacancy in the microbiology research group for a contract technician to work on the isolation and purification of enzymes from methane oxidising bacteria. Applications are welcomed from graduates and others with appropriate qualifications and experience in biochemistry and/or microbiology.

Salary will be either on the Technician Grade 2B Scale, £2,529 to £2,880 p.a. or Grade 3 at £2,688 to £3,069 p.a.

Apply by letter giving full details to the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 26/2T/78, by February 9, 1978. 1295(A)

**UNIVERSITY OF
LIVERPOOL
DEPARTMENT OF
BIOCHEMISTRY**

Applications are invited from biochemists for the postdoctoral post of Senior Research Assistant.

To work on the properties and regulation of synthesis of the ethanolamine ammonia-lyase of *Escherichia coli*. Enzyme formation appears to uniquely require the concerted action of two inducers. Familiarity with the concepts and techniques of bacterial genetics as well as enzymology would be advantageous. The post, tenable for a period of up to two years from a date to be arranged offers a salary in the range of £3,333 to £3,547 per annum with superannuation benefits.

Applications, together with the names of two referees, should be received not later than February 28, 1978, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/660/N. 1244(A)

**THAMES POLYTECHNIC
SCHOOL OF
BIOLOGICAL SCIENCES
RESEARCH ASSISTANT**

Applications are invited from good honours graduates in a biological discipline for the post of Research Assistant in the Division of Physiology and Cell Biology, School of Biological Sciences. The successful applicant will be required to work on the ultra-structural and cytochemical aspects of synapse formation in insects, under the supervision of Dr D. J. Beadle, and will be registered with the C.N.A.A. for a higher degree.

Salary: £2,778 to £2,940 inclusive. Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by February 14, 1978. 1240(A)

**UNIVERSITY OF READING
DEPARTMENT OF PHYSIOLOGY
AND BIOCHEMISTRY
POSTDOCTORAL
CARBOHYDRATE CHEMIST**

immediately required for up to two years for the synthesis of sugar derivatives and metabolites for W.H.O. sponsored research on the control of male fertility. Experience with radioisotopes an advantage. The Chemist will work with Professor G. M. H. Waites in the Department of Physiology and Biochemistry and Dr R. Khan in the Philip Lyle Memorial Research Laboratory, University of Reading.

Salary up to £3,761 per annum (under review). U.S.S. superannuation. Apply quoting Ref. M.N.02A, with curriculum vitae and two academic referees to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. 1274(A)

**THE LONDON HOSPITAL
MEDICAL COLLEGE
(University of London)
RESEARCH ASSISTANT
BIOCHEMIST**

Applications are invited for the appointment of Biochemist with good honours degree and also preferably a higher qualification, to join a small team investigating the physical biochemistry of articular cartilage and the intervertebral disc. This post is financed by a grant from the M.R.C.

Further enquiries to Dr A. Maroudas, tel: 01-247 5454, ext. 421.

Initial salary within the range £3,333 to £4,190 (under review) plus 100 London Allowance per annum.

Applications (two copies quoting RA/Biochem.2/78) together with the name of one referee to the Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, within 14 days. 1281(A)

**UNIVERSITY OF
EAST ANGLIA, NORWICH
FRESHWATER BIOLOGIST**

A post is available immediately as Research Associate to help investigate the limnology of the Norfolk Broads. The project will include water chemistry and invertebrate analyses as well as experimental work; field work will be carried out the year around and the ability to co-operate in a team is essential. The appointment will be for one year at a salary of £2,904 per annum, in the first instance but may be renewable for up to three years for a suitable person. Candidates should have a good honours degree appropriate to freshwater biology and should be able to drive. Applications should be sent as soon as possible to Dr Brian Moss, School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, and should quote two referees who are readily contactable. 1297(A)

**UNIVERSITY OF
NEWCASTLE upon TYNE
CHAIR OF ANATOMY**

Applications are invited for the Chair of Anatomy which will become vacant on April 1, 1978, through the resignation of Professor J. J. T. Owen. The Chair will carry with it the Headship of the Department of Anatomy for an initial period of five years which will be renewable. The candidate selected will be required to take up appointment as soon after April 1 as possible.

Salary will be in accordance with the Professorial scale, with membership of the appropriate superannuation scheme.

Further particulars may be obtained from the Registrar of the University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (15 copies), giving the names of not more than three referees, must be lodged not later than March 6, 1978. (Applicants from outside the British Isles may submit one copy only.) 1282(A)

**LONDON SCHOOL OF
HYGIENE AND
TROPICAL MEDICINE
(University of London)
Keppel Street, WC1E 7HT
DEPARTMENT OF
ENTOMOLOGY
TECHNICIAN**

required to assist for up to three years in a W.H.O.-funded programme on in vitro culture of human filariae using insect cell lines. Candidates should have H.N.C. in a relevant discipline. Applications in writing, giving full career details and naming two referees, should be sent to Secretary (A1). 1300(A)

**LONDON SCHOOL OF
HYGIENE AND
TROPICAL MEDICINE
(University of London)
Keppel Street, WC1E 7HT
DEPARTMENT OF
MEDICAL MICROBIOLOGY
BACTERIOLOGY UNIT**

Applications are invited from good honours graduates in the biological sciences, medicine or veterinary medicine for a post of Research Fellow, tenable up to three years, for research into microbiological pathogens in wildlife, with special reference to *Mycobacterium bovis*. Opportunities exist for the successful applicant to prepare for a higher degree. Salary, depending on experience, etc., in the range £3,377 to £4,640 inclusive. Applications, in writing, giving full career details and naming two referees, should be sent to the Secretary (A1). 1299(A)

**Central Birmingham Health
District
THE CHILDREN'S
HOSPITAL
TECHNICIAN or
BIOLOGICAL SCIENCE
GRADUATE**

required for a research post. The successful applicant will be concerned with a leukaemia and non-Hodgkins Lymphoma study. Previous experience in immunology helpful but not essential. Appointment for one year in the first instance.

Salary according to experience and qualifications.

For further details and an application form please contact Dr F. G. H. Hill, Consultant Haematologist, Haematology Department, The Children's Hospital, Ladywood Middleway, Birmingham B16 8ET. Telephone: 021-454 4851. 1246(A)

ASSOCIATESHIPS

**UNIVERSITY OF
CALGARY
GRADUATE
ASSISTANTSHIPS
(Teaching and Research).**

are available for students proceeding to the M.Sc. and Ph.D. degrees in all branches of CHEMISTRY and BIO-CHEMISTRY. The assistantships are valued currently from \$6,000 to \$7,000 per annum and carry remission of program fees and travel allowance. Positions are available beginning September 1978.

For further information write to: Department of Chemistry, Chairman of Graduate Studies, UNIVERSITY OF CALGARY, Calgary, Alberta, Canada T2N 1N4. Please indicate field of interest 1252(P)

**UNIVERSITY OF
MANCHESTER**

A Postgraduate Research Assistantship is immediately available for an APPLIED

MATHEMATICIAN

The successful candidate would work in the Department of Obstetrics and Gynaecology, in close collaboration with the Department of Mathematics, on problems in applied mathematics arising from the medical sciences. He or she may be expected to register for a higher degree. Appointment for one year in the first instance.

Salary £2,904 to £3,761 p.a. Superannuable.

Curriculum vitae and names of three referees should be sent to Dr B. S. H. Rarity, Department of Mathematics, The University, Manchester M13 9PL, as soon as possible. 1284(P)

STUDENTSHIPS

**AGRICULTURAL
RESEARCH COUNCIL
FOOD RESEARCH INSTITUTE
A.R.C. RESEARCH STUDENTSHIP**

Applications are invited from students for an Agricultural Research Council Studentship tenable from October 1, 1978 for up to three years at the A.R.C. Food Research Institute with a view to reading for the degree of Ph.D. at the University of East Anglia. The award is in the Microbiology Division where the student will work with Dr B. M. Lund on alkali-tolerant microorganisms from food wastes.

Details of the award are available from: The Secretary, A.R.C. Food Research Institute, Colney Lane, Norwich, Norfolk NR4 7UA, to whom application should be made in writing by February 28, 1978. 1230(F)

**THE WEST OF SCOTLAND
AGRICULTURAL COLLEGE
RESEARCH STUDENTSHIP**

Applications are invited for a Research Studentship in the Botany Department, to study the use of herbicides in the improvement of bracken-infested land. The award is tenable for up to three years, commencing in October, 1978, and the holder will be required to register for a higher degree.

Further details and application forms may be obtained from the Secretary, The West of Scotland Agricultural College, Auchincruive, Ayr KA6 5HW. 1249(F)

**S.R.C. "C.A.S.E." STUDENTSHIP IN
BIOMEDICAL ENGINEERING**

Applications are invited from Graduates or those hoping to graduate this year for a "C.A.S.E." award tenable now under the supervision of Dr G. W. Hastings in association with the Orthopaedic Department, North Staffordshire Royal Infirmary for work on development of an artificial tendon prosthesis for use in injured hands. Candidates should have a degree in Polymer Science or Technology, Materials Science, Fibre Science or Chemistry.

Apply to: Dr G. W. Hastings, Bio-Medical Engineering Unit, Medical Institute, Hartshill, Stoke-on-Trent,

enclosing curriculum vitae and addresses of two referees. 1256(F)

STUDENTSHIPS

continued from previous page

THE HANNAH
RESEARCH INSTITUTEfor Studies Relating to the Production
and Utilisation of Milk
AGRICULTURALRESEARCH COUNCIL
RESEARCH STUDENTSHIP

Applications are invited for an A.R.C. Research Studentship tenable for up to three years for research leading to a Ph.D. degree. Candidates should have, or expect to obtain in 1978, a 1st or Upper 2nd Class Honours Degree in an appropriate field. The successful candidate will be expected to carry out a research project in one of the following areas:

1. Hormonal control of amino acid metabolism;
2. Transport and metabolism of lipids;
3. Factors affecting the heat stability of milk;
4. Energy and protein metabolism in the cow.

Applications giving *curriculum vitae* and the names and addresses of two referees should be forwarded to:

The Secretary,
The Hannah Research Institute,
Ayr KA6 5HL,
by April 14, 1978, from whom further particulars can be obtained. 1289(F)

A.R.C. ANIMAL
BREEDING RESEARCH
ORGANISATION
POSTGRADUATE
STUDENTSHIP

Applicants are invited for an A.R.C. Research Studentship tenable in Edinburgh for three years from October, 1978.

The successful student will study the use of ultrasonic measurements on the live animal for the prediction of carcass quality with a view to obtaining a higher degree during the three years.

Candidates should have graduated, or be about to graduate in agriculture, agricultural science, zoology, physiology or a closely related field.

Awards include a tax-free allowance, payment of fees and other expenses. Full details and application forms are available from the Secretary, A.R.C. Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ, Scotland.

Applications should be made by March 4, 1978. 1268(F)

FELLOWSHIPS

UNIVERSITY COLLEGE OF
NORTH WALES, BANGORDEPARTMENT OF
BIOCHEMISTRY AND
SOIL SCIENCEPOSTDOCTORAL
RESEARCH FELLOWSHIP

Applications are invited for an S.R.C. Postdoctoral Fellowship (in collaboration with Professor W. Charles Evans) to undertake biochemical studies on the Anaerobic Metabolism of Aromatic Compounds by Micro-organisms.

The appointment is from March 1, 1978 or as soon as possible thereafter, and will be for a period of 22 months, ending on December 31, 1979.

Starting salary according to age and experience on Scale £3,333 to £5,627 per annum.

Applications (two copies), quoting reference 78/29, together with the names and addresses of two referees should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further details may be obtained. 1298(E)

RESEARCH FELLOWSHIP

IMPERIAL

CANCER RESEARCH
FUND LABORATORIES

Mill Hill, NW7

A postdoctoral Fellow is required to join a group working on the genetic and biochemical analysis of certain heat activated loci in *Drosophila melanogaster*, using cloned DNA fragments to investigate their organisation and expression.

Appointment will be for two years in the first instance with possible extension for a third year. Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr D. Ish-Horowicz (01-959 3236).

Applications with *curriculum vitae* and names of two referees, should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, by February 28, 1978. 1208(E)

UNIVERSITY OF
SALFORDDEPARTMENT OF
CHEMISTRY AND
APPLIED CHEMISTRYPOSTDOCTORAL
RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Research Fellow to work in association with Professor R. B. Cundall and Dr R. H. Bisby on a project sponsored by the M.R.C. entitled "The role of enzymic repair and chemical radiosensitisers in the yield of strand breaks in irradiated DNA."

Experience in radiation biochemistry desirable, but not essential.

The appointment is tenable for up to three years, commencing as soon as possible.

Salary within the range £3,333 to £3,761 p.a. with U.S.S.

Application forms obtainable from the Registrar, University of Salford, Salford M5 4WT (Telephone 061-736 5843) extension 215, to whom completed applications should be returned not later than Monday, February 27, 1978 quoting reference CH/217/N. 1291(E)

RESEARCH
FELLOWSHIP

A POSTDOCTORAL FELLOW required as soon as possible for an appointment of two years with possible extension to three years.

The work will be on the mechanisms by which viruses convert cells from a normal to malignant state, with emphasis on leukaemia-inducing viruses.

Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr J. Wyke (tel: 242 0200, ext. 267/270).

Applications with *curriculum vitae* and names of two referees, should be sent to:

The Secretary,
Imperial Cancer Research Fund,
Lincoln's Inn Fields,
London WC2A 3PX,
by March 17, 1978, quoting Ref. 61/78. 1209(E)

UNIVERSITY OF OXFORD

UNIVERSITY LECTURERSHIP IN
PHYSICAL CHEMISTRY

Applications are invited for a University Lectureship in Physical Chemistry, at a stipend according to age on the scale (under review) £3,333 at age 24 or under to £7,087 at age 42 or over, with superannuation. The post may be held in conjunction with a tutorial fellowship at University College, in which connection attention is drawn to the separate advertisement of this fellowship.

Further particulars of both posts may be obtained from Professor J. S. Rowlinson, Physical Chemistry Laboratory, South Parks Road, Oxford OX1 3QZ, to whom applications (six copies, except in the case of applicants outside Europe, who need send only one) with the names of three referees, should be sent by February 28, 1978.

FELLOWSHIP IN PHYSICAL CHEMISTRY,
UNIVERSITY COLLEGE

University College proposes to elect a Fellow and Praelector in Physical Chemistry. The post is open to men and women. The fellowship must be held in conjunction with the University Lectureship currently being advertised. Further particulars may be obtained from Professor J. S. Rowlinson, Physical Chemistry Laboratory, South Parks Road, Oxford OX1 3QZ, to whom applications should be sent by February 28, 1978. 1247(E)

UNIVERSITY OF
BIRMINGHAMRESEARCH FELLOWSHIP
IN GEOCHEMISTRY

Applications are invited for the above postdoctoral Fellowship in connection with a N.E.R.C. supported research programme to study the volcanic and plutonic rocks of the Scotia Arc and Antarctic Peninsula. Experience in igneous geochemistry is essential. The post is tenable for 22 months from April 1, 1978. Salary in the range £3,333 to £5,627. Maximum starting salary £4,190 (plus superannuation).

Applications (three copies), naming three referees, should be sent to the Assistant Registrar, Science and Engineering, University of Birmingham, Birmingham B15 2TT, by February 20, 1978. Please quote ref: NG2. 1269(E)

SITUATIONS WANTED

B.Sc., M.Sc. Pharmacologist, minor chemistry, experienced in the analysis of drugs in blood by polarography and glc, pharmacokinetics and statistical analysis of data with computer. Box 1257(B).

CONFERENCES

4th EUROPEAN
MEETING ON
BACTERIAL
TRANSFORMATION
AND TRANSFECTION
University of York,
York, U.K.

August 29–September 1, 1978

The following topics will be included in the programme:

DNA binding and uptake in
Transformation
Recombination in
Transformation
Plasmid Transformation
Transformation in Genetic
Engineering
Transformation Related to
Medicine
Transfection

Speakers will include: S. Lacks; M. Fox; G. Venema; A. M. Sicard; S. N. Cohen; G. Humphreys; F. E. Young; S. Erlich; P. F. Sparling; W. Wackernagel; T. Trautner.

Further details from: Secretariat, 4th European Meeting on Bacterial Transformation and Transfection, 142 Oxford Road, Cowley, Oxford OX4 2DZ, U.K. 1285(C)

LECTURES

N.A.T.O. ADVANCED STUDY INSTITUTE
1978 SUMMER SCHOOL on

"Synchrotron Radiation applied to Biophysical, Biochemical and Biomedical Research"

will be held in Frascati (Rome—Italy) from August 20 to September 1, 1978.

The subject will be covered by an international Faculty of outstanding lecturers. Lectures will be given in English in the format of a School to an audience of Scientists willing to use Synchrotron Radiation in their own field of Research. Persons willing to receive more information and application forms should write to:

Professor I. F. Quercia—Laboratori Nazionali
P.O. Box 56—FRASCATI
(Rome—Italy)
tel. 06/940262-06/941041

COURSES & SYMPOSIUMS

SCHOLARSHIPS

UNIVERSITY OF SALFORD
in association with the
PERKIN DIVISION OF THE CHEMICAL SOCIETY
International Symposium on
CHEMISTRY AND BIOCHEMISTRY OF PROSTANOIDS
will be held at

THE UNIVERSITY OF SALFORD
July 11-14, 1978

Symposium Chairmen

Dr S. M. Roberts (Salford) and Dr F. Scheinmann (Salford)
Invited Speakers will include:

- Dr W. Bartmann (Hoechst Aktiengesellschaft, Frankfurt)
Dr M. P. L. Caton (May & Baker Limited, U.K.)
Professor D. A. Van Dorp (Unilever Research, The Netherlands)
Professor J. Fried (University of Chicago, U.S.A.)
Professor P. A. Grieco (University of Pittsburgh, U.S.A.)
Professor E. W. Horton (University of Edinburgh, U.K.)
Dr R. L. Jones (University of Edinburgh, U.K.)
Dr S. Moncada (Wellcome Research Laboratories, U.K.)
Dr J. Muchowski (Syntex Research, U.S.A.)
Dr R. F. Newton (Allen & Hanburys Research, U.K.)
Dr C. Pace-Asciak (Hospital for Sick Children, Toronto)
Dr R. Pappo (Searle Laboratories, U.S.A.)
Dr J. E. Pike (Upjohn Company, U.S.A.)
Professor B. Samuelsson (Karolinska Institute, Sweden)
Professor C. J. Sih (University of Wisconsin, U.S.A.)
Dr D. Taub (Merck Sharp & Dohme, U.S.A.)
Dr E. R. H. Walker (I.C.I. Pharmaceuticals Division, U.K.)
Professor M. Vandewalle (Rijksuniversiteit-Gent, Belgium)
Professor Dr H. Vorbruggen (Schering AG, Berlin)

CONTRIBUTED PAPERS

A limited number of contributed papers have been accepted for the symposium.

Further details may be obtained from:

The Symposium Secretary (Short Courses Office)
Registrar's Department
University of Salford
Salford M5 4WT
Telephone: 061-736 5843 extension 449 1286(D)

First Soviet-Italian Symposium
on
MACROMOLECULES IN THE FUNCTIONING CELL

Sponsored by
USSR Academy of Sciences
Italian Society of Biochemistry
Capri (Italy)
May 25-27, 1978

Topics:

structure of eukariote genome;
genetic organisation of mitochondrial DNA;
genetic engineering,
mechanism of transcription,
RNA methylation and processing,
particular aspects of protein functions,
molecular basis of cell cycle and early stages of development.

Symposium Secretariat address:

Istituto di Chimica Organica e Biologica,
Via Mezzocannone, 16-80134 Napoli (Italy)
Ph. (081) 206411-206224.

1264(M)

**7th International Congress of Pharmacology
Satellite Symposium**

**RECENT ADVANCES IN THE PHARMACOLOGY
OF ADRENOCEPTORS**

University of Manchester, July 24-26, 1978

Topics included: electrophysiological consequences of adrenoceptor activation (smooth muscle, cardiac, gland and nerve cells); adrenoceptors and adenylate cyclase; molecular markers for adrenoceptors; release modulating adrenoceptors; functional significance of α - and β -adrenoceptors; clinical implications of α - and β -adrenoceptors.

Invited papers and contributed poster demonstrations.

Further information from Dr E. Szabadi, Department of Psychiatry,
University of Manchester, Manchester M13 9PT, U.K. 1273(M)

UNIVERSITY OF
ABERDEEN
M.Sc. IN UNDERWATER
PHYSIOLOGY

The scientific basis of human
diving and underwater medicine.

Applicants should have a good
honours degree in a Biological sub-
ject or a degree in Medicine. Appli-
cation forms and further details from
Dr A. G. Macdonald, Physiology
Department, Marischal College,
Aberdeen AB9 1AS. 1239(D)

FOURTH, WYE COLLEGE
SYMPOSIUM ON
NEUROPATHOLOGY
Wye College, Kent
July 17-21, 1978

A four-day residential symposium
related to the growing points in
Neuropathology and Neurobiology,
particularly directed at the younger
research workers.

Daytime Sessions include Quantita-
tion, brain development, behavioural
teratology, ageing, injury, blood-
brain-barrier and demyelination.
Evening Workshops on polypeptide
neurotransmitters, muscular dystrophy,
the motor end-plate and brain tumour
immunology.

For further information contact:
Dr C. H. Hawkes, M.D., M.R.C.P.,
Department of Neurology, Ipswich
Hospital, Heath Road, Ipswich,
Suffolk. 1238(M)

AWARDS

UNIVERSITY OF
EDINBURGH
FACULTY OF MEDICINE
**SCHOLARSHIP
FUND**

Applications are invited for
research awards tenable in the
Faculty of Medicine. Stipends are
at the following levels:-

Scholars with degrees in arts
or science £1,475 per annum;
Scholars with degrees in medicine
or dentistry and postdoctoral
fellows £3,500 per annum.

The awards include the pay-
ment of University fees and assist-
ance towards conference expenses.

Further details and application
forms, which must be returned
before March 17, 1978, may be
obtained from the Dean of the
Faculty of Medicine, University
of Edinburgh, Medical School,
Teviot Place, Edinburgh EH8
9AG. 1232(N)

THE NATIONAL KIDNEY
RESEARCH FUND

invites applications for grants for
renal research at units within the
United Kingdom. Application forms
are available from The Secretary,
184B Station Road, Harrow, Middle-
sex HA1 2RH (01-863 4469).
1258(H)

THE ROYAL SOCIETY
GOVERNMENT GRANT
FOR SCIENTIFIC
INVESTIGATIONS

Application for grants from the first
allotment of the Government Grant
for Scientific Investigations for the
year 1978 should be made not later
than March 15, 1978 on forms of
application to be obtained from the
Executive Secretary of the Royal
Society, 6 Carlton House Terrace,
London SW1Y 5AG.

Applicants must be British subjects
domiciled in the United Kingdom.
Grants may be made to promote and
support research in science and to
assist scientific expeditions and collec-
tions; but not for personal main-
tenance, payment of stipends or to
aid scientific publications. 1245(H)

THE AUSTRALIAN
NATIONAL UNIVERSITY
SCHOLARSHIPS FOR
Ph.D. DEGREE COURSES

Persons who hold, or expect to hold,
a bachelor degree with at least upper
second-class honours or equivalent
from a recognised University and who
have a capacity for research, are
invited to apply for Australian
National University Ph.D. Scholar-
ships, tenable over a wide range of
subjects in the Humanities and the
Physical, Medical, Chemical, Biologi-
cal, Earth and Social Sciences. Scholar-
ships are available in any of the depart-
ments or units of the Institute of
Advanced Studies which consists of
Research Schools of Physical Sciences,
Biological Sciences, Social Sciences,
Pacific Studies, Chemistry, Earth
Sciences and the John Curtin School
of Medical Research, of the School of
General Studies (Faculties of Arts,
Asian Studies, Economics, Law and
Science) or in one of the University
Centres.

Scholarship Benefits.

The basic stipend payable is \$A4,700
per annum (tax free) with additional
allowances for dependants and housing
assistance for married scholars. In
addition, return economy-standard air
fares and a grant towards removal
expenses are normally provided. (The
latter will not be provided for Aus-
tralian citizens overseas who are eligible
for Commonwealth Government
Research Awards.)

Tenure.

Scholarships are normally tenable for
three years and may be taken up at
any time of the year.

There is no set closing date, but
applicants from outside Australia are
advised to apply at least six months
before they expect to be available to
take-up a scholarship, if offered.

Full particulars and application
forms are available from the Academic
Registrar, The Australian National
University, P.O. Box 4, Canberra
ACT, 2601, or from the Association
of Commonwealth Universities (Appts),
36 Gordon Square, London WC1H 0PF
1229(H)

ARE YOU CONCERNED WITH THE QUALITY OF ENZYME-LABELLED ANTIBODIES?

**At the PASTEUR INSTITUTE,
we use for coupling only pure antibodies isolated by
affinity chromatography, and pure enzymes
of the highest specific activity.**

PURITY GUARANTEES QUALITY

**We are glad to offer the following products for your research
or clinical experimentation in the field of immunochemistry,
enzyme-immunocytochemistry, enzyme-immunoassay:**

Peroxidase labelled:

- Antibodies or Fab anti-human IgG (H + L)
- Antibodies or Fab anti-rabbit IgG (H + L)
- Antibodies or Fab anti-mouse IgG (H + L)
- Antibodies anti-sheep IgG (H + L)
- Antibodies anti-goat IgG (H + L)
- Antibodies anti-human IgA (specific α)
- Antibodies anti-human IgG (specific γ)
- Antibodies anti-human IgM (specific μ)

Also available on request:

- Antibodies or Fab coupled with glucose-oxidase, alkaline phosphatase, β -galactosidase.

For all information, contact:

Etienne Fayein - Institut Pasteur Production - Department of Laboratory Products
36 rue du Docteur Roux - 75725 PARIS CEDEX 15 - Tel. (1) 541.52.45 ext 138 - Telex 250609F

5000 Customized Research Diets

Custom formulation of research animal diets has been a specialty of ICN NUTRITIONAL BIOCHEMICALS for over 30 years. During this time we have formulated over 5000 specialized diets and have become experts in the area of research animal dietetics.

At ICN, diet components are subjected to extensive biological and microbiological assays, in fact the entire manufacturing process of each diet is rigidly controlled. In addition, our special pelletizing procedures assure you maximum uniformity and minimal feeding waste. Diet pellets are available in two

sizes and can be color coded to ease control of administration. With our knowledge in diet formulation you can rely on ICN NUTRITIONAL BIOCHEMICALS for the finest quality and most uniform product on the market.

To receive more information on any of our 100 standard diets or our customizing capabilities write for a free catalog or phone our Customer Service Department at (216) 831-3000. Special prices on large orders can be received by phone. Write or call your order today.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if *a* is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

9 February 1978

Little comfort for university teachers

Two and a half years ago the present Labour government of the UK introduced the first stage of a pay policy which is, of course, still in operation. In its first year the policy laid down that the maximum salary increase for anyone would be £312, and that those already being paid more than £8,500 per annum should get no increase at all. Succeeding stages have been equally tight-fisted. There can be little doubt that the policy has been effective in reducing the level of inflation from around the 25% per annum mark to the present 10%. But there have been obvious losers—the levelling nature of the policy has ensured substantial declines in real income for those paid above average, and the necessity for an arbitrary date of imposition in 1975 ensured that pay anomalies unresolved at that time remain unresolved. Nor in the present gradual thaw in incomes policy is there much comfort for those who live under the discipline of public sector cash limits or who are unable to negotiate deals on productivity. Into every one of these losing categories fall university teachers.

The 1975 clampdown occurred at a time when university teachers had gone to arbitration over their claim for the adjustment of parities with polytechnic staff and over a cost of living increase; they were left stranded. Everyone agrees that they have had a raw deal, and the salary scales speak for themselves: the lecturer scale starts at £3,333 per annum and professors can start as low as £8,100. At the low end of the pay scales, lecturers are widely able to claim social benefits that are intended for the poorer paid members of the community. More senior university teachers have seen their salary decline in real terms by up to 20% in the past few years, and by more when one includes 'fiscal drag'—the failure of tax rates and thresholds to move with the cost of living.

Even though there has been much hand-wringing by the government about the plight of university staff, it is not yet at all clear what the present negotiations between the Association of University Teachers (AUT) and the employers will yield. AUT, notably without industrial muscle, has said it is prepared to live with a rise that is consistent with the present 10% guidelines, but only with a firm timetable set for the elimination of the present anomalies. The union's expectation is that the anomalies would be removed by October of this year, and it has been handed a very fine precedent for such hopes by the firemen, who accepted an offer close to the guidelines only on the promise that they

would be well looked after in future years (assuming no change in the political complexion of the government). This form of agreement is not the sort of thing the government wants to repeat, however, and it has made the somewhat lame excuse that the firemen were unique because 'human life was at stake'. So university lecturers (who have actually increased their 'productivity' with significant increases in the student: staff ratio in the past few years, but who save no lives) are not held out much comfort.

The worrying thing in all this is not just the poor salary levels; it is a growing feeling that the Labour government is moving towards a perceptibly different style for universities without being entirely open about its intentions. A few weeks ago, the Commons debated the situation in the universities, including, of course, the pay problem, but much else besides. Two Labour MPs independently spoke about the need for greater public control of what goes on in universities, one going so far as to say that there was "a growing feeling in the country, particularly amongst younger Socialist politicians, that there should be a greater degree of public accountability for university funding". The Minister of State, Department of Education and Science, with special responsibility for higher education, Mr Gordon Oakes, did not exactly dissociate himself from such ideas, mentioning that the Labour Party had a discussion document on them, and going on to say that he hoped that in ten years "the university . . . will contain a 50-50 mixture—50 per cent coming from schools and 50 per cent who could be of any age".

From a minister, even to an almost empty House, this looks rather heavy stuff. Many, of course, will agree in general with his remarks about responsiveness but point out that a lot of universities, particularly those recently converted from colleges of advanced technology, scamper around quite a lot in an effort to meet the nation's wishes. But is he serious about a half-and-half university by 1988? Certainly there are demographic changes which will start to reduce the numbers of school-leavers after 1981, and certainly there is much scope for more continuing education. These most recent remarks, however, cannot but be unsettling at a time when university staff morale is not high. If ideas are indeed that advanced, the government should publish them, together with documentation, and give individual members of the university community a chance to have a reasoned discussion and give a sensible response. □

Saccharin: the risks and benefits

Bernard L. Cohen of the University of Pittsburgh argues that the decision on whether or not to ban saccharin should be taken in the light of risk-benefit analysis. The risk of cancer may be outweighed by the risks of obesity.

SCIENTIFIC decision-making in matters of public concern should be made on the basis of risk-benefit analysis; but in the controversy over the banning of saccharin there has been little evidence that this has been done. That controversy involves decision making by the general public, so it is important that the public understand the risks in some quantitative fashion.

Since the average person does not readily accept numbers, the best substitute is to compare the risks of saccharin with other risks with which members of the public are familiar. It is my purpose here to give both a risk-benefit analysis and to compare saccharin risks with other risks familiar in our daily lives. All calculations will assume a linear relationship between dose and effects as is customary in estimates of this type.

In the recent Canadian study of bladder-cancer patients (*Lancet*, 17 September 1977, page 578), a possible link was established between that disease and the use of saccharin such that if the United States population (2×10^8) were to ingest one diet soft drink each day throughout their lives, there would be an extra 1,200 bladder cancers per year. This implies a risk of 1,200 cancers per 7.3×10^{10} drinks, or one cancer per 6×10^7 drinks. There is ordinarily a time delay of 10 to 50 years between ingestion of a carcinogen and development of a cancer, so an average case would result in no more than a 20 year loss of life expectancy; thus, based on the results of the Canadian study, an average diet drink would reduce life expectancy by 20 yr/ 6×10^7 , or about 9 s.

To give a perspective on this number, smoking a single cigarette reduces life expectancy by 12 min (B. L. Cohen *American Scientist* 64, 550; 1977) so a diet soft drink is about 80 times less dangerous than a cigarette. From the above result (or from the original finding) it is straightforward to calculate that one diet drink per day throughout life causes a reduction in life expectancy, ΔL , of 2 d; or

$$\Delta L = 2 \text{ d} \left(\frac{\text{diet drinks}}{\text{d}} \right) \quad (1)$$

The benefits of diet soft-drinks result from their use in weight control by reducing calorific intake. Being overweight is well known to reduce life expectancy. In a rather old study, Pauling (*Proc. Natl. Acad. Sci.* 44, 619; 1958) analysed the data on this in a 1952 report of the Metropolitan Life Insurance Co. to obtain best fits to both a linear and quadratic relationship between loss of life expectancy, L , and overweight ($W - W_0$), where W is the weight and W_0 is the optimal weight. These were,

$$L = 17 \text{ yr} [(W - W_0)/W_0] \quad (2)$$

$$L = 36 \text{ yr} [(W - W_0)/W_0]^2 \quad (3)$$

Differentiating (3) and assuming that an average saccharin user would be at least 10% overweight and would weigh perhaps 160 lb gives

$$\Delta L = 0.05 \text{ yr/lb} \cdot \Delta W \quad (4)$$

Applying the same assumptions to (2) gives

$$\Delta L = 0.11 \text{ yr/lb} \cdot \Delta W \quad (5)$$

independent of the percentage overweight.

There is more recent data on this subject from the same source (*Metropolitan Life Insurance Co. Statistical Bulletin* 10; 1960). To quote typical figures, for a 45-year-old male with 150 lb optimal weight, weighing 170 lb reduces life expectancy by

1.5 years and weighing 200 lb reduces it by 4 years. This gives an approximately linear relationship with

$$\begin{aligned} \Delta L &= 0.08 \text{ yr/lb} \cdot \Delta W \\ &= 29 \text{ d/lb} \cdot \Delta W \end{aligned} \quad (6)$$

Since this is intermediate between (4) and (5) and is based on better data, I shall use (6).

An average person's body weight is related to his average daily calorie intake at about 1 lb per 14 calories per day. Multiplying this by (6) gives a change in life expectancy

$$\Delta L = 2 \text{ d/calories-per-d-intake} \quad (7)$$

From a comparison between (1) and (7) we see that diet soft drinks give a net benefit if one such drink reduces calorific intake by more than 1 calorie.

There seems to be no firm evidence on the amount by which diet drinks reduce calorific intake (or body weight). A non-diet drink has about 100 calories, so if all other things were unchanged, substituting diet for non-diet drinks increases life expectancy by 100 times more than the cancer risk reduces it. This is perhaps an extreme assumption, but it would be very difficult to prove that it over-estimates the reduction in calorie intake from diet drinks by a factor of 100. Unless this is done, there is no proof that the risk from diet drinks is greater than their benefits, and in fact it seems most likely that the opposite is the case.

If, on the other hand, we ignore the foregoing discussion and assume that there are no benefits from use of saccharin, it becomes important to understand the risks. We have already noted that ingesting a diet drink is 80 times less dangerous than smoking a cigarette, and we discuss here some other comparisons.

Perhaps the simplest risks to quantify are those due to automotive traffic. Approximately 8,000 people per year are killed in crossing streets in the United States. If the average American crosses five streets per day (3.5×10^{11} crossings per year), the risk per crossing is $8,000/3.5 \times 10^{11}$ or 2.3×10^{-8} . The risk from a diet drink is $1/6 \times 10^{-7}$, or 1.6×10^{-8} . Thus an average street crossing is about as dangerous as ingesting a diet drink.

Riding in automobiles involves a death risk of 2×10^{-8} per mile; thus a diet drink is as dangerous as one mile of automobile travel. Using a small car rather than a large car approximately doubles the risk. So purchasing a small car rather than a standard size car is at least ten times as dangerous (assuming 30 miles per day average driving) as ingesting one diet drink per day during the period of ownership.

Perhaps the best understood cancer risk is that of women not having an annual test for cervical cancer. The mortality risk from this neglect is about 6×10^{-7} per day, about 30 times higher than the risk of ingesting one diet drink per day.

The risk of one diet drink per day throughout life is readily calculated, using the Canadian study results, as $(1200/2 \times 10^8)$ risk per yr $\times 70$ yrs = 4×10^{-4} . Statistics show that the cancer risk varies considerably from one area of the country to another. For example, the risk is about 0.19 in New England compared to 0.15 in the south-east which has a similar age distribution. Thus moving from the south-east to New England involves 100 times greater cancer risk than ingesting one diet drink per day throughout life.

Approximately 7,000 Americans die each year due to fires, and it is estimated that about half of these could be saved if people would install smoke alarms in their homes (cost—about \$5 per year). Failure to install a smoke alarm is thus as dangerous as ingesting three diet drinks per day.

An endless list of comparisons could be put forward, but we have offered here a few examples that may be useful in helping understand the risk of saccharin. \square

Alternatives to sugar

The search for an ideal non-nutritive sweetener is almost a century old.

K. J. Parker outlines its history

SWEETNESS has long been known as a property possessed by many substances other than sugar, although their use as sweeteners has largely been confined to pharmacy, or precluded by toxicity. For example, chloroform, which was discovered in 1832, is still used for sweetening lozenges and linctus. The intensely sweet taste of liquorice root was known to the ancient Egyptians, an extract having been found in the tomb of King Tut (1500 B.C.). Although its strong liquorice flavour and pharmacological activity today limit its wider application as a sweetener, it is used in pharmacy, in some confectionery, and as a flavour potentiator.

The commercial development of artificial sweeteners dates from the discovery of saccharin in 1879, by C. Fahlberg and I. Remsen, followed by its manufacture five years later. In that year, the intense sweetness of *para*-ethoxyphenylurea was discovered by J. Berlinerblau, and within ten years, this compound was being marketed under the name of dulcin.

By the end of the last century sugar had become accepted as a basic food item, and its use and ready availability were taken for granted. Saccharin provided an alternative sweetener to sucrose, for use in times of sugar shortage, as a cheap substitute for carbohydrate sweeteners, or for inclusion in sugar-free diets. Its slightly bitter flavour and metallic after-taste, however, contrasting with the pure sweet taste of sucrose, reduces its acceptability. Consequently, the production of saccharin, which in Germany had reached 100,000 lb/year by the turn of the century and increased sharply during the two world wars, remained fairly static in Britain and Europe for the first half of this century.

Before 1940, inadequate nutrition had been a major concern of world health authorities. A decade later it began to be more widely appreciated that the converse—excessive or unbalanced food intake—could be equally injurious to health, possibly contributing to heart diseases, obesity and metabolic disorders. Since the need for essential dietary factors—vitamins, minerals, amino acids—was recognised, the emphasis for control of nutritional intake inevitably focused on carbohydrates and especially on sugar. Although the polemics of this particular view are still being debated, the substitution of sugar in the diet by a non-nutritive alternative has already

proved to be a painless and popular means of reducing carbohydrate—and hence, calorie—intake.

The demand for saccharin and its particular shortcomings meant that the market was ready for a more acceptable alternative. This was provided by a new sweetener, *N*-cyclohexylsulphamic acid, or cyclamate, discovered in 1937 by L. F. Audrieth and M. Sveda. In spite of its having only less than one tenth the sweetness of saccharin, the flavour of cyclamate was considered to be singularly pleasant and free from after-taste. Admixture of 10% saccharin effectively doubled its sweetness without introducing undesirable after-taste.

Legislation on sweeteners

The use of saccharin-cyclamate sweeteners, particularly in soft drinks, which currently accounts for some 70% of the synthetic sweeteners consumed, increased tenfold between their introduction and 1968. By then, concern was mounting over the potential hazard of unrestricted consumption of artificial sweeteners, especially by children, as a consequence of the widespread use of saccharin-cyclamate in non-dietetic foods and beverages.

A major manufacturer, Abbott Laboratories, had spent an estimated \$1 million on establishing the safety of this sweetener. Ironically, their disclosure that massive doses of cyclamate fed to rats was associated with the development of malignant bladder tumours in some of the test animals led in October 1969 to an immediate ban on the use of cyclamates in the United States. Great Britain, Canada and several other countries followed with equivalent legislation, though the restriction was not universal. Saccharin the only remaining permitted artificial sweetener, was subsequently removed from the Food and Drug Administration (FDA) list of food additives generally recognised as safe (GRAS list). Finally, in March of this year, following the results of at least six separate studies on rats in which cancerous tumours were positively identified, the use of saccharin in diet foods, cosmetics and non-prescription drugs was ordered to be withdrawn in the United States within two years, under the controversial 1958 Delaney amendment to the 1938 Food, Drug and Cosmetic Act. The Delaney clause makes mandatory the banning of the food use of any substance shown to induce cancer in any animal under any conditions.

It was against this background of an increasingly urgent demand for a safe non-nutritive sweetener that research into the chemical basis of sweetness was boosted in the late 1960s. In spite of the extensive research into the physiology and psychology of taste perception, however, it is still not possible to predict the chemical structure of an ideal non-nutritive sweetener, or even that a substance will be sweet. Many types of compound are known to taste sweet, but in every class the initial discovery of sweetness was accidental. There seems to be no common molecular property which can be used to predict the ability to elicit a sweet taste.

Theoretical models have been advanced for the molecular basis of sweetness, the most comprehensive being that of Robert Shallenberger of Cornell University. In its most recent form, his model accounts for the perception of sweetness in terms of a three-point interaction with the taste receptor protein, involving a proton donor, a proton acceptor and a lipophilic group sited at the points of a precisely specified triangle. In spite of the ingenious explanation of the sweetness of known compounds, however, not all compounds fitting the model are sweet and the theory cannot be used to predict or construct radically new sweeteners.

Nature and nurture

Research into new sweeteners thus takes the form of molecular variations on a known structural theme. Alternatively, intensely sweet substances of natural origin can be sought and characterised. Either approach, however, is ultimately subject to the requirement that the candidate sweetener should meet the increasingly rigorous toxicological safety standards imposed by the public health authorities, before it can be permitted for use as a food additive. Since toxicity cannot be predicted on the basis of molecular structure either, the search is inevitably speculative.

Since the ban imposed on cyclamate, Abbott Laboratories have been continuing to sponsor research into the toxicology and safety of cyclamate, and in November, 1973, petitioned the FDA for its reinstatement on the grounds of need and in the light of further experimental evidence. It is argued that the single piece of evidence indicting cyclamate was not substantiated by subsequent studies. With the

eventual withdrawal of saccharin there will be no permitted sweetener on the US market, a situation in which the FDA may be obliged to reconsider rescinding the earlier ban on cyclamate, though so far the Abbott petition has not been allowed.

New synthetic sweeteners

Several candidate sweeteners are being developed, but very little published information is available. The market is highly competitive, and no wonder for production of a multi-billion dollar sweetener is the prize.

In addition to cyclamate, two other non-caloric sweeteners, Aspartame and β -neohesperidin dihydrochalcone, have been under consideration by the FDA, though neither has yet been declared wholly acceptable. The intense sweetness of the methyl ester of the dipeptide α -L-aspartyl-L-phenylalanine was discovered by James Schlatter working in the G. D. Searle & Co. laboratories and reported by R. H. Mazur, J. M. Schlatter and A. H. Goldkamp in 1969, though the compound had been first synthesised three years previously within ICI. Searle filed a patent for the use of this compound as a sweetener, while ICI patented the cyclohexyl analogue at almost the same time.

Since this discovery, several hundred closely related compounds have been synthesised, many of which have proved sweet. However, Searle decided to develop and market the original dipeptide methyl ester under the name of Aspartame, in conjunction with the Japanese Ajinomoto Company, which had independently developed a cheaper synthetic route. The possible formation of the cyclic self-condensation product diketopiperazine, formed in soft drinks on storage, for example, resulted in Searle voluntarily withholding the product from the market, even though qualified approval had been granted by the FDA in 1974 for the use of Aspartame as a table sweetener. Then in December, 1975, the FDA rescinded its earlier order indefinitely, pending further review of the evidence on safety, in spite of the removal of earlier fears on the carcinogenic properties of diketopiperazine.

In a study of the bitter principles of citrus fruit rind, R. M. Horowitz and B. Gentili discovered that the bitter flavanone naringin from grapefruit peel could easily be converted into the corresponding dihydrochalcone which by contrast was found to be intensely sweet, a property shared by a number of related dihydrochalcones. Of these β -neohesperidin dihydrochalcone was selected for toxicological and metabolic studies by the Southern Regional Laboratory of the US Department of Agriculture. The pilot plant production was also developed making possible its

manufacture in ton quantities when required. Although its low solubility in water and the delay in taste perception make this sweetener unsuitable for many applications, once granted food additive status it could be used for sweetening chewing gum, toothpastes, pharmaceutical preparations, etc where such properties are not a disadvantage.

A new class of sweeteners, the oxathiazinone dioxides, was reported in 1973 by K. Clauss and H. Jensen of Hoechst. These, like saccharin and cyclamate, contain the sulphonamide group and a lipophilic part. The β -methyl derivative, which has been reported to have the best flavour profile, is being developed by Hoechst under the name Acetosulpham. It has ap-

Wild serendipity berries

proximately one third the sweetness intensity of saccharin.

Although several amino acids are known to taste sweet, it was discovered accidentally, by Kornfeld of Eli Lilly and Co., that some 6-substituted D-tryptophan derivatives are intensely sweet. Of these, 6-chlorotryptophan, reported to be approximately 1,000 times as sweet as sucrose, has been selected for development as a sweetener by the company.

A systematic study of the relationship between taste and chemical structure of a series of terpene oximes and related compounds has been undertaken by a research team at Stanford University led by E. M. Acton. The intense sweetness of the α -syn-oxime of perillartine was first reported in 1920 by Furukawa in Japan, although this compound is unsuitable for use as a sweetener owing to its low water solubility. However, a closely related oxime has been proposed as a suitable candidate sweetener by the Stanford group.

Since the early discovery of the intense sweetness of alkoxyaromatic amines—examples of which are Dulcin and, more recently, the deep yellow P 4000, used briefly as a sweetener in

Holland during the war—numerous intensely sweet arylamines have been described. These compounds are generally toxic, and are thus unlikely to be selected for further development. However, A. Zaffaroni, of the Dynapol Corporation of America, has conceived the idea of linking a sweet molecule to a non-absorbable, inert polymer in such a way that the taste interaction of the sweet part is unaffected. Not being metabolised, the sweetener cannot manifest systemic toxicity and is non-caloric.

Why sugars and polyhydric alcohols reach a limiting level of sweetness with sucrose, while non-hydroxylic compounds of similar molecular weight can be several orders of magnitude sweeter

Thaumatococcus plants

can be explained by the absence of a lipophilic group from the sugar molecule. Pursuing this theme, Michael Lindley and Gordon Birch of the National College of Food Technology, Reading University, prepared several methyl ethers of sucrose but none was found to be particularly sweet. This approach was vindicated, however, with the discovery by Leslie Hough and S. P. Phadnis of Queen Elizabeth College, London, of the intense sweetness of tetrachlorogalactosucrose, while working in collaboration with Riaz Khan of Tate & Lyle, on deoxy- and halodeoxysucrose derivatives. They subsequently showed that sweetness reaches a maximum in 1',4,6'-trichlorotrideoxygalactosucrose, found to be approximately six hundred times sweeter than sucrose. It has a pure sweet flavour closely similar to that of sucrose. Although it has been shown not to be toxic to rats and to be non-caloric, its suitability as a non-nutritive sweetener has yet to be established.

Natural sweeteners

The occurrence of high-intensity sweeteners in nature has long been recognised, many having been used traditionally for generations: for ex-

ample, glycyrrhizin from the roots of the liquorice plant, the fruit of the South Chinese Lo Han Kuo and the leaves of the Paraguayan shrub *Stevia rebaudiana*. Stevioside, a triterpene glycoside, which is readily extracted from the leaves of *S. rebaudiana*, is being produced on a commercial scale in Japan by the Toyo Menka Karishma Company. Stevioside, which is approximately 300 times sweeter than sucrose, is not a permitted food additive elsewhere.

More recently the serendipity berry (*Dioscoreophyllum cumminsii*) was identified in a broad survey of sweet fruits undertaken by George Inglett and J. F. May, Department of Agriculture, in 1968. Its berries are intensely sweet owing to the presence of the protein monellin which is approximately 2,000 times as sweet as sucrose. A similar protein, thaumatin, has been isolated from the fruit of a West African plant *Thaumatococcus daniellii* by H. van der Wel and K. Loeve of Unilever. This has proved to be the sweetest substance known, being

around 4,000 times sweeter than sucrose. The extraction, purification and properties of both monellin and thaumatin have been studied extensively, in particular by Tate & Lyle, who are able to produce thaumatin in kilogramme quantities. However, the toxicology of thaumatin has not been fully evaluated, though, being a vegetable protein which has been consumed for generations, it seems unlikely that it would have harmful side-effects.

Similar considerations would seem to apply miraculin, the glycoprotein extracted from the berries of the bush *Synsepalum dulcificum*, also native to West Africa. An extract of this fruit, which has the property of tasting intensely sweet only in the presence of acids, was marketed for a time by the Miralin Corporation of America who established extensive plantations in several countries to produce the extract. However, FDA approval for this product was denied in 1974 pending toxicology testing, with the consequence that it is not now commercially available.

Naturally occurring sugars and sugar alcohols, such as fructose, xylitol and maltitol, are also being evaluated as alternative sweeteners, though since they are metabolised, they cannot be regarded as non-caloric. Xylitol, produced from birch wood, is available at ten times the price of sugar. It is finding use as a sweetener in chewing gum, though it is not a permitted sweetener in Britain and, following recent evidence of potential carcinogenic activity, may be prohibited in the US.

In spite of the intense interest worldwide in developing alternative sweeteners, the ideal non-nutritive sweetener—water soluble, chemically and thermally stable, of pure flavour, non-toxic, and of high sweetness intensity—has not yet been discovered and may still be some years off. In the meantime a less satisfactory compromise seems inevitable. □

K. J. Parker is General Manager, Research, with Tate & Lyle Limited.

No soft options in Carter's energy research policy

ENERGY policy was a major plank in Jimmy Carter's campaign platform during the 1976 Presidential election. In a year when the rising cost of imported oil was causing increasing economic concern, and the late E. F. Schumacher was telling capacity audiences that "Small is beautiful", Carter promised that, if elected, he would shift the emphasis of US energy technology away from a prime dependence on nuclear fuels and towards non-nuclear alternatives, in particular renewable resources such as solar power.

But like many other campaign promises—for example that to reduce the budget of the Defense Department, now scheduled for a 9.4 per cent increase to \$117.8 billion in fiscal year 1979—Carter's energy plans have, in the face of established institutional positions and interests, undergone considerable revision in his first year of office.

The President has maintained his firm stand on the dangers of proliferation resulting from the production of plutonium by fast breeder reactors, in particular demanding the closure of the Clinch River liquid metal fast breeder reactor at Oak Ridge, Tennessee.

But the administration is still pursuing a vigorous nuclear policy through other options, including possibly a major design project for a thorium-

cycle reactor. And already last year, following, in particular, moves to speed up the licensing of new reactors, Carter's earlier claims that he would turn to nuclear energy only as "a last resort" were beginning to wear thin.

Further confirmation that energy policy has changed little comes from analysis of the Department of Energy's proposed research and development budget for the fiscal year 1979. In presenting this to Congress two weeks ago, President Carter has suggested that the overall level of energy R&D remain roughly static at \$2.7 billion.

The budget contains considerable increases in commitments to research on synthetic fuels (another area in which campaign promises seem to have been forgotten). In contrast, resources for research into renewable energy sources show little change. It is proposed, for example, to raise the budget for windpower research from \$37 million to \$41 million; and solar power research, which has grown from \$4 million in 1974 to \$193 million in 1977 and \$303 million last year, will increase only to \$309 million. The increases in these two topics scarcely keep up with the expected increase in the cost of living.

There are, admittedly, some important shifts in philosophy reflected in the budget proposals. Perhaps the

The inauguration of the US National Aeronautics and Space Administration's windmill in New Mexico

Steve Northrup NYT Pictures

most significant is a hefty 27% increase in funds for conservation R&D, under which funds for research on topics such as motor efficiency and energy storage will be increased from \$301 to \$381 million.

In addition, the proposed closure of the Clinch River fast breeder project, the subject of a furious political battle last autumn, after which Carter vetoed the authorisation bill and is yet to decide what to do with a supplemental appropriation of \$80 million passed by Congress, would save \$150 million, creating an apparent swing in emphasis from nuclear to non-nuclear technology.

But apart from the Clinch River project, there has been little change in relative priorities. Indeed if the Clinch River funds are extracted from the 1978 budget figures, the proportion of R&D expenditure going to other nuclear projects actually increases between 1978 and 1979, from 45.8 to 46.4 per cent of the total for research and technology development.

There is therefore still a strong continuation of pre-Carter policy directions. Dr John Deutch, who recently moved from chairman of the department of chemistry at the Massachusetts Institute of Technology to become director of the Office of Energy Research, told a House Subcommittee last week that "the strategic approach to our nation's energy R&D efforts has been evolving over the last several years".

But if there has been no obvious shift in priorities, there has been a significant change in strategy. In presenting the President's proposed R&D budget two weeks ago, Dr Frank Press, director of the Office of Science and Technology Policy, said that the administration was trying to shift the emphasis of R&D funding away from development projects—considered the responsibility of private industry—towards more basic research.

Dr Deutch shares this strategy, although he puts it slightly differently. In an interview with *Nature* last week he pinpointed the problem in energy research as lying not at the level of basic science, in which the department's position is relatively strong, but at an intermediate point in the R&D spectrum which he identifies as "advanced development work". In this he includes fields such as geology, and chemical and process engineering.

Dr Deutch also stresses the need to maintain flexibility in research programmes, developing a "hedged" strategy and keeping options open, so that the department can respond quickly both to new research potentials, and to changing parameters affecting energy supply.

In the nuclear field, for example,

one criticism of the Clinch River project has been that its massive funding has required putting too many eggs into one basket, and that the project was an attempt to move too fast in a single direction when revised predictions of future energy demand are indicating that the speed may be premature.

In contrast, the administration is suggesting that a close look should be taken at a wide range of options in the nuclear field, and at an earlier stage than project development. Thus within an overall R&D budget that is virtually static, funding for "basic energy sciences" is being increased by 20 per cent from \$177 million to \$212 million, and for nuclear research and applications by 22 per cent from \$227 to \$278 million. 'Advanced technology and assessment projects', which will involve a mechanism for monitoring and providing a critique of R&D programmes, will be increased almost three-fold, from \$8 million to \$21 million.

One alternative that President Carter is known to be particularly enthusiastic about is the thorium cycle reactor which, by using the thorium-uranium conversion process rather than the uranium-plutonium process, would be much safer than the conventional fast breeder.

Carter's enthusiasm for the thorium cycle is not shared by the environmentalist lobby, many of whom feel that it still fails to meet adequate safety criteria, at least in comparison with once-through light water reactors. But the Department of Energy is expected to announce soon a major \$15 million project for the conceptual design of a 650 to 900 megawatt reactor, to fill the programme gap left by terminating the Clinch River project; and the thorium cycle is a high contender for this new design.

Dr Deutch said last week that he felt

there was still not sufficient stress on solar research and development. But in line with the administration's general approach to R&D, funds for "production, demonstration and distribution" of solar energy supply are being reduced from \$87 million to \$64 million in 1979.

The decision to limit the growth of solar research funds has not been a popular one in Congress, where solar energy, with its apparent promise as a pollution-free, virtually infinite resource, carries a strong and populist appeal. Pointing out in the House of Representatives that the cutbacks in the solar energy programme were more than the salary increases requested by the Department of Energy, Representative Louis Frey Jr of Florida claimed that the budget could be characterised as "one giant step backward in energy research and development."

There will be a powerful campaign to increase solar energy's share of the R&D budget when the latter is debated in committee. And the campaign will receive added fuel from a shortly-expected report from Congress' General Accounting Office, which is thought to suggest that as much as \$600 million—almost twice the amount proposed by the administration—could be fruitfully absorbed into existing and proposed solar energy research projects.

In itself, the apparent conflict between the administration and Congress is not too important. In areas known to have enthusiastic support on Capitol Hill, the administration is often claimed to feel safe in going for a low budget knowing that it will be increased, and that it can put in higher bids in areas which Congress traditionally cuts back.

But in this case the stakes are higher than usual. President Carter has publicly asked to be judged by the success of his energy policy; hence his frustration at the stalemate on energy legislation, and the important symbolic role that it has taken on. However, in cutting back on solar energy research and continuing to emphasise nuclear options, whatever the administrative and scientific logic, he stands to lose the confidence of precisely those whose support he needs to push through his whole energy policy.

As one environmentalist who has been closely involved with recent debates said last week, in words that have been echoed across a range of issues: "I'm obviously disappointed that Carter's going back on his campaign promises, but I'm more disappointed that he won't admit what he's doing, that he won't come out and say that he has changed his mind."

Bangladesh sets up institute of nuclear agriculture

THE Vice-President of the Bangladesh Republic officially inaugurated the Institute of Nuclear Agriculture (INA) last month. This Institute, set up in collaboration with the International Atomic Energy Agency (IAEA), is the fourth large one of this kind to be built. The others are in Yugoslavia, India and Brazil. The Institute has been established in the premises of Bangladesh Agricultural University with the objective of identifying and solving the basic agricultural problems of the country through interdisciplinary approaches employing both nuclear and conventional techniques.

Agriculture is the mainstay of the Bangladesh economy. Farm products alone account for about 55% of the Gross Domestic Product (GDP), so the importance of boosting productivity can hardly be over-emphasised at a time when the country is facing the joint problems of food shortage and a fast growing population.

The initial research programmes of the Institute are in plant physiology, plant genetics, soil science, and ento-

mology, with emphasis on improving varieties of rice, jute, wheat, pulses, tomato and oil seeds. INA has already achieved some encouraging results in evolving new rice varieties, such as IRRATOM-24 and IRRATOM-38 through irradiation technique. They are capable of higher yield and early maturing than mother variety IRRI-8. Similarly, the two new strains of jute known as ATOMPAT-8 and ATOMPAT-38 have been found superior to the mother, D-154.

Mr Hellio F. S. Bittencourt, Deputy Director General of IAEA, addressing the inaugural ceremony said that the application of nuclear techniques in agricultural research was by no means a luxury for the developing countries; it was the base proven method for solving certain practical problems of agriculture.

The Swedish International Development Agency (SIDA) has provided a grant of over one million US dollars towards the cost of equipment, advisory service and fellowships, IAEA being the executant agency.

Less paper, more money for US scientists

DR FRANK PRESS, director of the US Office of Science and Technology Policy, has launched a major campaign to encourage Government agencies to reduce the amount of time that university scientists receiving federal support are required to spend on paperwork.

Speaking in Washington last week, Dr Press said that the money that could be saved in this way might amount to millions of dollars for every university.

"One of the goals of this administration is to make universities perform better the basic research which the government subsidises. One way of reducing paperwork and overheads, for example, would be to award longer-term grants, so that scientists do not have to be writing new research proposals every three months or so."

Dr Press said that the Department of Health, Education and Welfare, which is responsible for the research carried out by the National Institutes of Health, is already looking at ways in which it can help universities by reducing paperwork and streamlining regulations about grants.

"I have also written to NASA (the National Aeronautic and Space Administration) and to NSF (the National Science Foundation) asking them what their plans are on this," he said.

Dr Press said that, under the current legislative framework, the administration could not guarantee support for a particular research project over a two or three year period, since the research budget had to be approved annually by Congress.

"However we can say to someone that we intend to support his work for a given number of years, and that if he or she sends in a report on the progress of his work at the end of each year which is satisfactory, we will agree to further funding." The Science and Technology committee of the House of Representatives is already looking into the possibility of multi-year authorisations as a way of stabilising the research-funding process, he said.

Dr Press also said that although there was little support in the administration for setting up a Department of Science, there was growing interest in establishing a Department of Technology and Industrial Development.

"Many countries, such as Germany, England, France and Australia, already have such ministries. This could be an interesting direction for the administration to go, particularly since there is an increasing sensitivity at Cabinet level to the problems of industrial innovation."

The facts about Kosmos-954

RECOVERY of the fragments of Kosmos-954 is proving, not surprisingly, a lengthy operation, and although some sizeable pieces have apparently been located and taken for examination to White Shell, Manitoba, it may be some considerable time before any hard facts are available about the type of satellite and reactor actually involved. Although the figure of 50 kg U-235 has been tossed around fairly freely, this is simply an assumption the reactor involved was of *Romashka* type. This is the only Soviet reactor of comparable type ever described in open publications; accordingly, it is the only basis for speculation. The *Romashka* has a 40 kW thermal yield and was, indeed, designed for space use, and assuming that such reactors are still used aboard certain Soviet satellites, it is possible to work out tentative figures for radiation hazards for this, and possible future, satellite crashes.

Three scenarios have been discussed among the experts. The first—break-up of the satellite in the stratosphere—requires the use of additional data. This comes from the US Navy SNAP-9A, powered by a plutonium source, which disintegrated before entry into orbit in 1964. On this basis, assuming an initial charge of 50 kg U-235—and 100 days in orbit before disaster, one arrives at the comforting figure that six months after the incident the residual radioactivity would be of the order of 10^{-9} of the International Commission for Radiological Protection safety level. (This is the concentration of airborne radioactivity that could be breathed 24 hours a day without harm.)

For break-up on impact, the downwind distance to which the UK Medical Research Council emergency reference levels extend works out at the order of a few km. (This means in effect that beyond this distance the hazards of mass evacuation are considered to be greater than the risk from radiation). For impact in one piece, if no chain reaction occurred, initial radiation levels would be expected of 1 rad/h at 200 m from the site, 100 millirad at 500 m, 10 millirad at 1500 m. Had the impact occurred in a populous area, evacuation would have been necessary up to 2 km, if no intervening shielding (e.g. masonry) were present. Chain reaction is unlikely, since the mass of uranium used in such satellites is normally subcritical, and special methods, e.g. a reflector, must be used to keep sufficient neutrons within it to maintain a chain reaction. Such a reflector would virtually certainly become

detached and destroyed during uncontrolled descent.

However comforting or worrying these figures, there is no doubt that the gloomy prediction of Ecclesiastes that "they shall be afraid of that which is high" has taken on a new and urgent meaning. President Carter has already expressed his willingness to be a party to a treaty banning the use of reactors from orbit. For the Soviet side, Academician Leonid Sedov has said in a TASS interview on Soviet radio that the errant satellite was in no way the "flying nuclear bomb" which some "absurd rumours" would make it. There were not and could not be any weapons aboard, he said, and those who spread such tales were trying to undermine the basic principles of international cooperation in the exploration and peaceful use of outer space.

In spite of Sedov's reassurances, it seems likely that Kosmos-954 did have certain military potentialities. Technically, it was a low orbit satellite for ocean surveillance. The presence of a reactor aboard (as opposed to a weaker isotope source) implies the use of powerful radar for monitoring ship movements, which would suggest that the terms of reference of the international agreements on the peaceful uses of both space and atomic energy were being somewhat stretched. Any future agreement on reactors in orbit might well have to re-examine the definition of 'peaceful' in this context.

Doubtless as a further reassurance, Sedov presented the official Soviet view of the accident: a sudden depressurisation of the satellite while beyond the range of Soviet tracking facilities. Since depressurisation was so rapid, it is assumed that Kosmos-954 collided with "some other object of natural or artificial origin".

Strangely, Sedov gave the significant date as January 6—the date of the "depressurisation". Yet according to US observers, the satellite was already misbehaving on December 17. The two reports are not incompatible—if the satellite was already out of control, it might well have come into contact with some other artificial object or debris which it normally should not have encountered. This, however, is not Sedov's story: he maintains that the on-board systems became inoperative only as a result of the January 6 impact—one more minor mystery to add to the story of Kosmos-954.

One fact, however, has already emerged quite clearly—the cost of the search and recovery operations. According to Canadian Prime Minister Pierre Trudeau, by last weekend this had reached one million dollars and was rising daily.

Vera Rich

Britain's big science on the baseline

AFTER four months in office, Professor Geoffrey Allen, Chairman of the UK's Science Research Council (SRC), is pleasantly surprised that the Advisory Board for the Research Councils (ABRC) is not as hostile to basic science as he had been led to believe by his predecessor, Sir Sam Edwards.

Professor Allen, speaking at a British science writers' luncheon, said that in spite of the proposed 1.7% annual cut in the SRC's budget over the next four years, announced with the science vote last month, the outlook for science in the UK is looking slightly up. His cautious optimism is founded on the ABRC's decision to award the SRC greater shares than it could expect, in proportion to its annual expenditure, of the extra £4 million added to the science vote last October, and of the £4.5 million to be spent on capital work in 1978/79.

A beneficiary of that optimism could be 'big science', long since neglected for research designated of national importance. "Nuclear physics, astronomy and space research have been battered" admits Professor Allen. For nuclear physics, in particular, he agrees that funding is now at the minimum viable level—almost. "We've nearly reached the baseline" he says, "which we must maintain to support a UK presence in nuclear physics".

And Professor Allen seems determined to have a say in the fate of British nuclear physics. Last December, he was at his own request appointed to the Council of the European Centre for Nuclear Research (CERN) in Geneva, now the major recipient of Britain's funds for high energy physics. He has already expressed his view that CERN's annual budget should be planned to remain at a plateau of about Sw Fr 560 million. The budget for 1978 is Sw Fr 615 million and many countries would like to see future budgets stabilise at about Sw Fr 600 million.

Not all British nuclear physicists, however, are in agreement with Professor Allen's baseline. Dr G. Stafford, Director of the UK Rutherford Laboratory thinks that a Sw Fr 560 million budget at CERN "will mean losing out on basic experiments". Such a low sum, he claims, "takes no regard for future development. By the 1980s existing machines will be old and at that level of funding we would not be able to replace them". On one point, though, Allen and Stafford do agree; that if future projections for the total UK nuclear physics budget are met, involving a 25% cut in spending over

the next five years, then there would be insufficient funds for a home-based programme and UK nuclear physics would be at an end. Stafford feels that the funding is at an absolute minimum.

The fate of high energy physics, however, is being pursued on another level. At the end of this week, Shirley Williams, Secretary of State for Education and Science, and a powerful lobbyist for the interests of scientists in the UK cabinet, will visit CERN.

The state in Britain of the other big science—astronomy and space science—is perhaps not quite so critical as that of high energy physics. Provided that there is no large cutback in funds over the next few years, radio astronomers should be able to maintain a competitive programme. Plans for a millimetre-wave radio telescope already have SRC approval: all that is now needed is Treasury approval for the £4.5 million it is likely to cost. And Jodrell Bank has plans to go ahead with extending its multi-telescope interferometer at an estimated cost of £2 million.

In astronomy it is the X-ray astronomers and space scientists who are showing most concern over their futures. Professor Ken Pounds of Leicester University claims that British X-ray astronomy is in a "fairly critical state". Its international reputation is higher than it has ever been but the prospects for the future are poor unless funding can be maintained at least at the present level. "If the UK is to get the best out of its subscription to the European Space Agency (ESA), then it must have a comparable home programme". But ESA can only fund one major new project in any particular discipline every two years, so each discipline is catered for approximately once every ten years. At the moment, for example, ESA has only one satellite for X-ray studies, EXOSAT. Therefore the UK must be able to bid for space on other satellites including NASA's Space Shuttle. This means maintaining a home based programme to the tune of £5-6 million.

Professor Allen's concern, however, is not entirely with the problems of 'big science'. He sees as one of his immediate priorities "making Sam's plans succeed" by continuing to give special attention to areas of national importance including microelectronics, marine technology and polymer engineering and making sure that schemes to improve collaboration between industry and universities are implemented.

Skylab coming down

OFFICIALS at the US National Aeronautics and Space Administration are concerned that Skylab, last used in 1974 and still, at 85 tons, the largest manmade object in earth orbit, could fall to earth later this year.

Originally it was planned that Skylab would stay in orbit until 1980, when a manned space shuttle could attach a rocket motor to it that would send it into a higher orbit, or initiate a controlled re-entry.

Recent calculations, however, indicate that Skylab, which cost \$294 million to launch, could crash into the atmosphere later this year, and NASA officials are now working on a plan to command the still-operable steering rockets to send Skylab into a controlled tumble that would speed up re-entry.

The manoeuvre would be carefully calculated to bring the station back to earth on a steep descent over a broad area such as the Indian Ocean or the South Pacific. □

Letter from Sakharov and Meiman

IN October 1977, the US Association for Computing Machinery informed their Soviet opposite numbers that they would not cooperate with or sponsor international conferences in the Soviet Union until the Soviet attitude to human rights, exemplified by the case of Anatolii Shcharanskii, improved. Recently the ACM received the following message:

To the Association for Computing Machinery; to US scientists and engineers in computer technology

Distinguished Gentlemen, We'd like to express to you our deep gratitude for your resolute actions on behalf of Anatolii Shcharanskii. You have hit just the right nail. The Soviet authorities extremely appreciate the cooperation in science and technology, thus, there is nothing to induce them so factually and effectively as a refusal to maintain

this cooperation.

We'd feel happy if your actions were followed suit by physicists on behalf of Professor Yurii Orlov and Andrei Tverdokhlebov, by biologists and medical specialists on behalf of Sergei Kovalev, as well as by writers and editors on behalf of Aleksandr Ginzburg.

Your courageous and noble stand is not simply ethically the best but the only practical one. Do not believe and do not take seriously any assertion that your decision allegedly could only embitter the Soviet authorities and aggravate the situation of Soviet scientists. Do not doubt that your human and professional solidarity will bring positive results.

*Nobel prize winner, Academician
A. Sakharov*

*Professor of Mathematics
N. Meiman*

CORN (maize) is the principal grain crop of the United States. Cash receipts from corn in the US in 1969 were nearly twice as much as for soybeans, and almost three times as much as for wheat. Peanuts (groundnuts) netted only 7% of the dollar value for corn. They have since become nationally prominent for presidential reasons. Peanuts, like soybeans, are legumes; they fix nitrogen and their seeds are good sources of proteins. Peanut protein is better balanced with respect to amino acids than is corn protein, but it is low in lysine, methionine and threonine.

Corn, in damp weather, and peanuts are good hosts for the growth of a mould, *Aspergillus flavus*, that produces aflatoxin, a potent carcinogen. The Food and Drug Administration (FDA) and the 'Delaney Clause' smiled benignly on aflatoxin, which is produced by God rather than the chemical industry, and is therefore not bannable. An 'action level' of 20 ppb of aflatoxin is used as a guideline for regulation. This level is carcinogenic in laboratory animals. In 1974, the FDA proposed to replace this level by a tolerance of 15 ppb for peanut products. Presumably this was intended to lower the cancer risk from aflatoxin somewhat, but the modest retreat is scarcely in accordance with the principle of total exclusion so sternly embodied in the Delaney Clause.

On 14 November, an FDA spokesman announced that 66 life-time cancers per 100,000 persons could develop from normal or expected ingestion of aflatoxin-contaminated pea-

nut and corn products. Presumably this figure would correspond to about one case per 100,000 persons per year. It was based on a combined estimated consumption of 2 ppb of aflatoxin from peanuts and 10 ppb from corn

Corn and Peanuts

THOMAS H. JUKES

products. This cancer rate may be compared with about 33 per 100,000 for lung cancer deaths, usually largely attributed to cigarette smoking, and about 168 for all US deaths from cancer. The estimate for aflatoxin corresponds to about 2,000 cancer cases for the entire US population.

I assessed the cancer hazard from diethylstilbestrol (DES) in beef production as not more than one case in 2,500 years in the entire US popula-

tion, based on pessimistic figures. This estimate, for some reason or other, was not challenged by the FDA lawyers who cross-examined me on 4 November at the hearings on DES in meat production. Perhaps this rather striking difference between hazards from DES and aflatoxin should be pondered by the FDA in setting priorities on bureaucratic regulations.

Aflatoxin should also be considered by vegetarians who tell us that we should eat corn, rather than feeding it to cattle, because we need to be less wasteful of food. The same school of thought advocates eating plant proteins, such as those of soybeans and peanuts, as replacements for beef and pork. However, when cattle and pigs eat corn and other feeds that contain injurious substances, they may filter them out, excrete them or metabolise them, especially if they are water-soluble. Being in a high position on the 'food chain' may have its advantages, even though we are frequently told that this is not the case.

The most active substances that inhibit mould growth belong to the antifungal group of the currently-criticised chemical pesticides. Also, oddly enough, the toxic effect of aflatoxin in rats can be reversed by dosing with DDT.

Two years ago an outbreak of hepatitis, with more than 100 deaths, was reported in India, associated with the consumption of corn that was contaminated with aflatoxin. Affected people could have consumed 2 to 6 mg daily for a month. About 1000 persons who recovered are being followed for liver cancer.

correspondence

GDR's state of science

SIR,—Under this presumptuous title your journal, which has built its reputation on a claim of fair and objective reporting, saw fit to publish the 'impressions' of an anonymous correspondent of his visits to unnamed biochemistry and microbiology laboratories in an undisclosed city of the GDR (13 October, page 548). The picture on the same page intimates that it might have been Leipzig. As a biochemist at the Karl-Marx University of Leipzig I feel that the readers of *Nature* deserve substantial factual information to do justice to the heading chosen by the editors.

The state of biochemistry is of course part of the general development of sciences in the GDR. In the last ten years alone funds for science have increased more than threefold and the percentage of the GNP going to science and technology has increased from 2 to 5. The life sciences have had their fair share in this development. As far as biochemistry is concerned it may suffice to mention that of the seven departments in medical faculties six are housed in new buildings (Rostock, Berlin, Leipzig, Halle, Jena, Magdeburg). In the Academy of Sciences there have been founded eight institutes of life sciences with a sizeable representation of biochemistry, in particular in the Institut für Molekularbiologie, Berlin-Buch, and the Institut für Biochemie de Pflanzen, Halle. All establishments are headed by prominent scientists rather than by administrators. The development of research in the life sciences is largely based on prognostic documents, worked out by some hundreds of scientists themselves, which have been accepted by government as a framework for implementation.

The vast majority of scientists in the GDR go along with the tenets held by most thoughtful scientists elsewhere—that freedom of research is tied indissolubly to social responsibility. All scientists loyal to the GDR have equal chances regardless of creed and there is certainly no pressure to join the Socialist Unity Party or any other. As far as the spirit of young biochemists is concerned all I have experienced is enthusiasm rather than despondency. There is a general feeling of social security and optimism shared by the scientists with all citizens of the GDR which is based on the record of uninterrupted progress of our socialist society which does not know economic

crises or unemployment. There is of course no denying that we wish to have more foreign exchange at our disposal for more equipment, literature and travels. But we know that this depends in the first line on the efforts of our workers to increase export.

As far as conditions at the Karl-Marx University are concerned, scintillation counters, analytical and preparative ultracentrifuges from internationally renowned manufacturers as well as the internationally leading biochemical journals are in fact available. The Karl-Marx University maintains an effective cooperation with British universities and biochemists.

For many years there has been a regular exchange of staff and students, biochemists included, between the Karl-Marx University and the universities of Leeds, Manchester and York. Two biochemists of the Karl-Marx University, one of them myself, are members of The Biochemical Society of Great Britain.

The growth of biochemistry is reflected in the number of members of the Biochemische Gesellschaft der DDR, whose membership has doubled over the past few years and now totals 610. The scientific life is an active one and a multitude of national and international meetings are held including the Federation of European Biochemical Societies (FEBS) Advanced Courses. It is to be hoped that a good many readers of *Nature* will participate at the 12th FEBS Meeting to be held in Dresden, 2–8 July, 1978 and will be able to judge for themselves both the general state of life and of science in the GDR.

E. HOFFMAN
Karl-Marx Universität, Leipzig, GDR

Discarding the diet-heart hypothesis

SIR,—No, Mr Rivers (3 November, page 2), I am not a heretic, I am a scientist. Science is for me a religion both because it opens an endless wonderland and because it works. It is, in a needy world, a way to solve problems, as are Buddhism and Christianity and Judaism and the other religions, each in their own way. The way science works is quite simple but not widely understood. Using the best available evidence the scientist formulates an hypothesis and then he and his peers set out to disprove that hypothesis. We never prove in science, we advance to new understanding by

disproofs. The hazard, as Platt has so eloquently said in his essay 'The step to man', is that scientists may become so enamoured with some favourite hypothesis that they never test it. Or they become intrigued with the testing hardware and dawdle or they refuse to accept the disproving results of good tests. The last has happened with the diet/heart hypothesis. A noisy clutch of scientists is defending, excusing, delaying, procrastinating over the decision to discard a disproven hypothesis. Their tactics prevent progress.

Sir Andrew Huxley was lately quoted (8 September, page 95) as saying that the most sinister behaviour for scientists is to refuse to test an hypothesis (say the inheritance of intellectual ability) because it would be thought socially or politically wicked to raise a question whose answer might disagree with some preconception. No less sinister is the tactic of the diet/heart enthusiasts who, by their noisy propaganda hope to coddle and prolong the diet/heart hypothesis. That hypothesis has been shown wrong by scientific method. I believe that because I believe in the scientific method.

The heretics, Mr Rivers, are selling corn oil.

GEORGE V. MANN

Nashville, Tennessee

Research and culture

SIR,—It is sad, when it comes to defending support for basic science, that *Nature* editorialists should resort to stating the obvious, that is that basic research is a cultural activity ('How much further can the pendulum swing?' 27 October, page 743).

Sad but not surprising, considering how many educated persons, including scientists, seem to ignore this fact or are confused by the distinction between civilisation and progress. Civilisation is culture. Encouraging cultural activity is maybe the best investment for the future of a nation; it is an investment in enlightenment, a non-depreciating quality (whether or not research comes up with the cure for cancer—that would be progress).

After talking with friends in the British theatre, however, who have been out of work for a while now, it might not be such a good idea, after all to remind the government that research is a cultural activity.

GIUSEPPE ZACCAI
NORINE ZACCAI

Domène, France

news and views

Our picture of the organisation of genes in higher organisms has recently undergone a revolution. Analyses of eukaryotic genes in many laboratories¹⁻¹⁰, studies of globin, ovalbumin, immunoglobulin, SV40 and polyoma, suggest that in general the coding sequences on DNA, the regions that will ultimately be translated into amino acid sequence, are not continuous but are interrupted by 'silent' DNA. Even for genes with no protein product such as the tRNA genes of yeast and the rRNA genes in *Drosophila*, and also for viral messages from adenovirus, Rous sarcoma virus and murine leukaemia virus, the primary RNA transcript contains internal regions that are excised during maturation, the final tRNA or messenger being a spliced product.

The notion of the cistron, the genetic unit of function that one thought corresponded to a polypeptide chain, now must be replaced by that of a transcription unit containing regions which will be lost from the mature messenger—which I suggest we call introns (for intragenic regions)—alternating with regions which will be expressed—exons. The gene is a mosaic: expressed sequences held in a matrix of silent DNA, an intronic matrix. The introns seen so far range from 10 to 10,000 bases in length; I expect the amount of DNA in introns will turn out to be five to ten times the amount in exons.

This model immediately accommodates two aspects of the genetic structure of higher cells. Heterogeneous nuclear RNA clearly is the long transcription products out of which the much smaller ultimate messengers for expressed polypeptide sequences are spliced. The unexpected extra DNA in higher cells, the excess of DNA over that needed to code for the number of products defined genetically, now is ascribed to the introns.

What are the benefits of this intronic/exonic structure for genes? For the sake of argument let us assume that the splicing mechanism is general and independent of the specific gene or the state of the cell, reflecting simply some secondary structure in the RNA. For example, base-pairing in the messenger could generate sites which would serve as signals for enzymes, such as those that excise tRNAs from their precursors, to cut out a section. The cut would be

Walter Gilbert is American Cancer Society Professor of Molecular Biology at Harvard University.

Why genes in pieces?

from Walter Gilbert

resealed by an RNA ligase. Even if RNA processing is general, the presence of infilling sequences can speed evolutionary

Single base changes, the elementary mutational events, not only can change protein sequences by the alteration of single amino acids but now, if they occur at the boundaries of the regions to be spliced out, can change the splicing pattern, resulting in the deletion or addition of whole sequences of amino acids. During the course of evolution relatively rare single mutations can generate novel proteins much more rapidly than would be possible if no splicing occurred.

Furthermore, the splicing need not be a hundred per cent efficient; changes in sequence can alter the process so that base pairing and splicing occurs only some of the time. Even mutations in silent third base positions, could modify the joining so that the products of a single transcription unit can be both the original gene product and a new product, also synthesised at a high rate. Evolution can seek new solutions without destroying the old. A classic problem is resolved: the genetic material does not have to duplicate to provide a second copy of an essential gene in order to mutate to a new function. Rather than a special duplication, the extra material is scattered in the genome, to be called into action at any time. After a new gene function appears, if a higher level of product is needed, there will be selective pressure for gene duplication (as well as pressure for the loss of the introns in highly repeated genes). One consequence of the intronic model is that the dogma of one gene, one polypeptide chain disappears.

A gene, a contiguous region of DNA, now corresponds to one transcription unit, but that transcription unit can correspond to many polypeptide chains, of related or differing functions.

Recombination now becomes more rapid. Since the gene is spread out over a larger region of DNA, recombination, which should be hampered in higher cells by the inability of DNA molecules to get together, will be enhanced. Furthermore, if exonic regions correspond to functions put together by splicing to form special combinations in the finished protein, then recombination within introns will assort these functions independently. Middle repetitive sequences within introns may create hot spots for recombination to rearrange the exonic sequences.

Recombination within introns will generate curious genetic structures for eukaryotic genes. Structural mutations should be clustered, separated by long distances from mutations in other exons. Mutations in different functions may be interspersed, when one product's intron becomes another's exon.

According to this view, introns are both frozen remnants of history and as the sites of future evolution. Nevertheless, they could also have other roles. Specific recombinations between introns can bring together exons into a transcription unit to make special differentiation products. Specific new splicing patterns could be turned on by special gene products. A differentiation pathway may be determined by the appearance of a new splicing enzyme, calling forth new proteins out of the heterogeneous nuclear RNA.

On this can be based a striking hypothesis to explain the behaviour of immunoglobulin heavy chains. At an early stage of the immune response a single lymphocyte can synthesise two different immunoglobulins, IgM and IgD, with the same idiotype; two different constant portions attached to the same V_H region. This may be the result of a V_H region translocating by recombination within an intron near the constant genes so that a transcription unit is formed for a $V_H-C_H-C_\delta$ message. Splicing can then create contiguous messenger sequences for V_H-C_H and V_H-C_δ chains. The switch from IgM to IgG might be a new translocation of the V_H gene, but, alternatively, it may be a new enzyme that changes the processing of a $V_H-C_H-C_\delta-C_\gamma$ message to produce a V_H-C_γ product. □

Restriction endonucleases: a new role *in vivo*?

from Richard J. Roberts

FEW enzymes have been exploited as thoroughly as the bacterial restriction enzymes. In recent years they have been instrumental in dramatic advances in DNA sequence analysis, genetic engineering, and studies of gene structure and function. Yet surprisingly little is known of their biological role. It has become almost axiomatic to associate them with a defence mechanism by which bacteria insulate themselves against invasion by unwelcome foreign DNA. This view has its origins in the genetic phenomenon of host-controlled restriction and modification. Two enzymes mediate this process: an endodeoxyribonuclease (restriction enzyme) which degrades DNA, and a methylase (modification enzyme) which protects DNA against the action of the restriction enzyme. Because both enzymes coexist in the same cell, the cell's own DNA is protected by the action of the methylase, whereas incoming foreign DNA, which lacks the proper modification, is susceptible to destruction by the restriction enzyme.

Two different types of restriction enzymes have been found and can be distinguished by their mode of cleavage. Although both recognise a specific sequence within a DNA molecule, the Type I enzymes cleave at random sites remote from that sequence and give heterogeneous products, while the Type II enzymes cleave at specific sites within or close to the recognition sequence. It is these latter enzymes that have enjoyed such popularity as the molecular scalpels of the biochemist. Perhaps the best-known example is *EcoRI* from *Escherichia coli* which recognises the sequence, G^+AATTC , and cleaves at the site indicated by the arrow. It produces specific fragments which carry short, single-stranded extensions at each end allowing them to reanneal and become a substrate for a DNA ligase. Thus, any two *EcoRI* fragments can be joined, which has made possible the powerful techniques of genetic engineering.

But paradoxically, the very enzymes which are thought to prevent the exchange of DNA *in vivo* are precisely those which facilitate that exchange *in vitro*. Could it be that the restriction enzymes have a dual role *in vivo* and catalyse both degradation and synthesis just as they do *in vitro*? This possibility has been raised previously but until now it had not received serious attention. It seemed unlikely that bacteria could be as smart as molecular biologists, but apparently they are. For recent

experiments by Chang and Cohen (*Proc. natn. Acad. Sci. U.S.A.* 74, 4811; 1977) show that an *E. coli* strain carrying the *EcoRI* restriction enzyme can indeed mediate genetic engineering *in vivo*. In a series of elegant experiments, they have demonstrated that a variety of site-specific recombination events can be catalysed *in vivo*.

Their experiments centred around the fact that a chloramphenicol (Cm) resistance gene contains an *EcoRI* site located so that cleavage will inactivate the gene. Restoration of gene activity requires precise rejoining at the *EcoRI* site. It was first shown that such precise rejoining could be accomplished *in vivo* by transfecting *E. coli* with two *EcoRI* fragments, each containing a part of the Cm resistance gene. Chloramphenicol-resistant transformants were recovered. Then a plasmid, pSC352, was constructed in which the same Cm gene was inactivated by the insertion of an *EcoRI* fragment. Transfection of pSC352 into an *E. coli* strain (C600, pMB4) which contained the *EcoRI* restriction enzyme resulted in a few transformants (6×10^{-5} of all transformants) which had acquired Cm resistance. *In vitro* analysis showed that such transformants arose from precise excision of the inserted *EcoRI* fragment. In more extensive experiments, they showed that *EcoRI* promoted site-specific recombination could involve multiple and physically separate fragments of plasmid DNA. In each case, the plasmids used for transformation were prepared so as to be unmodified against the action of the *EcoRI* restriction enzyme. What if the sites are already modified? To answer this question, Chang and Cohen propagated pSC352 in *E. coli* C600 (pMB4), where it is modified by the *EcoRI* methylase, and then observed the frequency of excision of the inserted fragment under normal growth conditions. Chloramphenicol-resistant clones developed with a frequency of about 10^{-9} . In this case, therefore, even the presence of the correct modification enzyme within the cell was insufficient to prevent site-specific recombination.

Although the observed frequency of these events *in vivo* is extremely low, their importance should not be underestimated. They raise anew the question of the biological role of restriction enzymes, and have implications for the current heated controversy about *in vitro* recombinant DNA experiments. Because these observations were made in the laboratory, it is difficult to assess their relevance to processes which might occur in the natural environment. Nevertheless, even if they occur at the low frequency observed by Chang and Cohen, the

magnitude of the bacterial population on the face of this Earth would still mean that the phenomenon could be of considerable importance to bacterial evolution. Such a possibility has been raised previously (Reanney *Bact. Rev.* 40, 552; 1976). Clearly, it is necessary that experiments be carried out under conditions resembling those *in vivo* for if indeed bacteria routinely exchange genetic information in this way, such exchange would not be limited to DNA originating from prokaryotes. We would be forced to the conclusion that species barriers exist, not because of a physical barrier to the exchange of genetic information, but rather because a functional barrier prevails. If such is the case, it would surely provide the strongest argument against the strict regulation of recombinant DNA experiments *in vitro*.

This question of frequency has other profound implications. If the frequency can be raised in the laboratory, then it may be possible to construct recombinant DNAs in this way. Shotgun experiments might merely require transformation of the appropriate strain with intact DNA. In this way, both the biochemistry and the present regulations could be circumvented. Of course, ethical questions remain and, presumably, the next round of guidelines for recombinant DNA research will take account of these new observations. It will be of some interest to see how they are phrased. Perhaps all experiments involving recombination, whether *in vivo* or *in vitro*, will fall under their jurisdiction; this could include the whole of classical genetics. Even the most ardent bureaucrats will find it impossible to regulate recombination in the environment. Plants, insects, animals, do it all the time. The line may have to be drawn in the laboratory. There sex will require a Memorandum of Understanding and Agreement, while elsewhere it remains unrestrained. □

A hundred years ago

THE New York *Tribune* gives an account of a public exhibition in that city of Edison's Phonograph, which seems to have been very successful. The tones reproduced by the vibrating disk of the machine were so distinct that they could be heard and understood in different portions of the crowded room.

From *Nature* 17, Feb. 7, 291; 1878.

Richard J. Roberts is a Senior Staff Investigator at the Cold Spring Harbor Laboratory.

A RELIABLE method of assessing the mutagenicity of chemical and physical agents in mammalian cells would be invaluable. Visible chromosome damage such as breaks, and translocations has been used, but has proved rather disappointing so far; it is not as sensitive as could be wished, and while it can be effective for heavy doses of some mutagens, such as X rays, it often yields unsatisfactory results in terms of normal dose rates of ingested substances (as seen for instance in the confused literature on chromosomal breakage and LSD). Perry and Evans (*Nature* **258**, 121; 1975) showed that the number of sister chromatid exchanges (SCEs) per cell is a far more sensitive indicator of exposure to both physical and chemical mutagens than is the number of visible chromosomal aberrations, but it has not yet been proven that the presence of increased numbers of SCEs necessarily indicates actual damage to the genetic information of the cell. But now Carrano *et al.* (page 551 of this issue) have provided stronger evidence that the number of SCEs seen in cells after treatment with a range of known mutagens may be directly related to genetic damage and mutation rate, in which case it could represent a sensitive and easily quantified test of mutagenicity.

Sister chromatid exchange can be seen in chromosomes studied at the metaphase stage of cell division. At this stage each chromosome is made up of two equal chromatids which arise when the chromosomal DNA is replicated at the synthetic (S) phase of the cell cycle, a few hours before cell division starts. If material has been exchanged between these two sister chromatids by the metaphase stage it means that DNA breakage and repair must have

Testing for mutagenicity

from E. H. R. Ford

taken place between S phase and metaphase. Precise interchange of material need not of itself alter the genetic information of a cell, so the significance of visible SCE as a measure of possible genetic damage or mutation has not so far been clear.

Although SCE was described by J. H. Taylor *et al.* 20 years ago (*Proc. natn Acad. Sci. U.S.A.* **43**, 122; 1957), using an autoradiographic technique, it is only since S. A. Latt (*Proc. natn Acad. Sci. U.S.A.* **70**, 3395; 1973) introduced an optical method for differentiating sister chromatids that SCE has readily been studied. A newly replicated chromatid which has incorporated the thymidine analogue BUdR can be differentiated from its older sister by fluorescent, Giemsa staining or immunological techniques (since the BUdR quenches the fluorescent or staining property of the chromatin).

The baseline SCE frequency in untreated human lymphocytes is 5–15 per cell (Latt & Juergens in *Population Cytogenetics* (Eds Hook, E. B. & Porter, I. H., Academic Press, 237; 1977). Alkylating agents such as ethylmethanesulphonate, mitomycin C or nitrogen mustard (which can all also induce visible chromosomal damage) considerably increase the number of SCEs per cell at concentrations where no other visible morphological damage is caused to chromosomes, indicating that SCE number is a sensitive test for chromosome damage.

Carrano *et al.* have now shown that

in Chinese hamster ovary cells there is a strong and linear relationship between the induction of SCEs and of mutations producing resistance to 8-azaguanine (mutations mainly at a particular locus, the hypoxanthine phosphoribosyl transferase (HPRT) locus.) They used four mutagenic agents; the alkylating agents, ethylmethanesulphonate (EMS) and N-ethyl-N-nitrosourea (ENU), mitomycin C (MMC) which is also a cross-linking agent, and proflavine sulphate (PRO), which intercalates into DNA. Each agent produced increases in the SCE and mutation rates, and for each there was a linear relationship between SCE and mutation rate—but this was different for each agent. ENU was the least efficient inducer of SCEs compared with mutations, and MMC the most efficient. The authors have been able to calculate the number of mutations per cell which correspond to one SCE, ranging from 0.08 for MMC to 1.2 for ENU.

If certain extrapolations can be made, namely that the marker used gives a representative mutation rate comparable to that at other loci, that human cells behave similarly to those of the Chinese hamster and that the SCE/mutation ratio *in vitro* can be extrapolated to cells *in vivo*, it would be possible to estimate the mutagenicity of various physical and chemical agents simply by counting the number of SCEs found in human lymphocytes.

Carrano *et al.*'s findings need to be confirmed and the validity of these extrapolations determined. But if Carrano *et al.*'s suggestions are confirmed we may soon have a greatly improved, simple and direct method of assessing the mutagenicity of all sorts of agents.

Preplanetary disk?

from Andrew Fabian

THE formation of stars is shrouded by dust. The massive gas clouds within which they form by gravitational collapse are cold and seeded with dust grains. Optical radiation from the newborn star is scattered and absorbed by these dust clouds, then reradiated at infrared wavelengths. Consequently it is often easier to deduce more about the properties of the gas and dust than the star. This means that little is known observationally about this important phase of a star's life.

From a theoretical point of view the situation is somewhat happier, at least until the observations improve. The collapse and fragmentation of a cold gas cloud under gravity has been discussed for decades. Problems emerge,

not the least of which are to do with the rotation and magnetisation of the star. Perfectly spherically symmetrical collapse seems most unlikely, especially when it is recalled that stars are observed to rotate at speeds up to and approaching breakup speed. Many stars are, moreover, members of binary (or multiple) pairs in orbit about each other. A collapsing rotating gas cloud is likely to flatten out and form a disk with a bulge in the centre—not too dissimilar in shape to our Galaxy. The bulge will form the stars and the disk what? Planets perhaps?—A tempting possibility considering the disk-like concentration of the major and many of the minor bodies of the Solar System. Gravitational collapse is halted within the central star, at least for the time being, by the onset of nuclear fusion, but accretion will continue within the disk until it is dispersed. Turbulent or magnetic viscosity in a disk as dense as might be associated with a newly

forming star causes matter to spiral in at the expense of angular momentum, which flows outward. We have our friend the accretion disk, which has been much discussed in the context of accretion onto black holes, both in X-ray binaries and galactic nuclei. A start was made on modelling accretion disks around newly formed stars a few years ago by D. Lynden-Bell and J. Pringle (*Mon. Not. Roy. Astr. Soc.* **168**, 603; 1974). Clearly, observational evidence of such a disk around a newly formed star is of great interest.

R. I. Thompson, P. A. Strittmatter, E. F. Erickson, F. C. Witteborn and D. W. Strecker have made a good start (*Astrophys. J.* **218**, 170; 1977) by combining their own infrared spectra of some highly reddened emission-line objects with unpublished optical continuum data of one of the objects taken by S. Grandi. MWC 349 and LK H α 107 are objects from the Mount Wilson, and Lick, catalogues of emis-

Andrew Fabian is at the Institute of Astronomy, University of Cambridge.

sion-line objects. Both objects appear to be newly formed stars embedded in dense gas and dust clouds. The ultraviolet radiation of such bright young stars rapidly photoionises the surrounding gas and is thereby completely absorbed. Recombination within the resulting HII region is then responsible for the bulk of the observed emission lines. Reversing this reasoning, we see that a study of the strengths of such lines ought then to be a monitor of the ultraviolet flux of the star. Such a technique has been employed for some time, but in the case of these highly obscured objects, the emission lines must be dereddened before any reliable estimate may be made.

This is where the combination of aircraft and ground-based infrared spectroscopy comes in, for the Paschen and Brackett lines of hydrogen are much less affected by the dust reddening than the optical Balmer lines. A comparison of observed line ratios with those predicted on the basis of recombination within an HII region allows an extinction curve to be obtained. The authors use the strength of Brackett γ to estimate the emission measure of the HII region and thence (with a distance estimate) the spectral type and properties of the central star. In the case of MWC 349, a 30 solar mass 06.5 star is implied. Whilst other emission lines and radio data are consistent with this result, the observed visual magnitude is not. The inferred star is about 11 times too faint to account for the observations when reddening (using the enormous dereddening factors deduced above) is included. This might be due to a mistake in the reddening corrections, but there are problems, too, with the known 40-year brightness decrease of this object, and the flatness of its optical continuum, both of which are uncharacteristic of isolated stars.

The authors thus invoke another component—a preplanetary disk which is accreting onto the central star. It is easy to show that the long wavelength spectrum of such a disk is flatter than that of a star if both radiate as blackbodies. The inner regions of the disk are hottest, but have a smaller area than the cooler outer regions and the balance gives a spectral slope of 1/3, in agreement with the optical data. At ultraviolet wavelengths the stellar radiation dominates the ionisation of the HII region, but the disk is assumed dominant in the optical. An accretion rate is thereby deduced which together with the 40-year variability timescale suggests a disk mass at least 1% that of the Sun.

Whilst the evidence does not decisively indicate an accretion disk, or demonstrate that planets would or could form in such a disk, it does seem that the authors are justified in claim-

ing that "MWC 349 is certainly by far the best now known candidate for a

newly formed star with a surrounding preplanetary disk." □

Nations and numbers 1977

from Robert M. May

EACH year, the Environmental Fund (1302 Eighteenth St, Washington, DC) pulls together UN and other estimates, to produce a large chart of population data for individual countries, and for regional groupings. In addition to population magnitudes, and birth, death and net growth rates, the chart gives a changing selection of other statistical information pertaining to aspects of the human condition. In 1975 this included country-by-country patterns of age structure and urbanisation (see *News and Views* 261, 12; 1976), and in 1976 the number of acres of arable land per person, and the past and present figures for import or export of cereal grain (*News and Views* 265, 101; 1977).

All these numbers are uncertain. In the past, I have indicated some of the reasons, for countries as different as the USA and China. There is a major discontinuity between the Environmental Fund's world figures for 1976 and for 1977, which stems from a revision in the Indian population data. Previous numbers had been based on the 1974 population, as estimated by the International Statistical Program Center (ISPC) of the US Bureau of the Census; increasing this by the reported population growth rate gives around 657 million Indians in 1977. ISPC and the UN now base their estimates on the 1973 Indian census, giving a new figure of 642 million in 1977. This at a stroke erases 15 million bodies from the estimated world population. As the Environmental Fund notes, it also "indicates that either one or two Indian censuses were grossly in error or that Indian vital statistics are vastly worse than had been generally supposed". In eight other countries (Guinea, Ivory Coast, Senegal, Madagascar, Cameroon,

Lesotho, Saudi Arabia, United Arab Emirates) the results of new national censuses indicate population sizes greater than had been thought.

Overall, the world population in mid-1977 was around 4,307 million, growing at an average rate of 2.1% per annum. Highest growth rate was in Libya, with 4.1% per annum; Kuwait's 6.1% was disqualified, as influenced by immigration. Lowest was Portugal, with -0.4%. Many of the local differences in average population growth rates (for example 3.6% in Gaza versus 2.1% in Israel) have political consequences.

Regional patterns over the sweep of the past 27 years are interesting. Since mid-1950, the world population has grown from around 2,543 to 4,307 million, representing an average growth rate of 2.0% per annum over that period (as contrasted to the 1977 figure of 2.1%). The regional components are as set out in the table.

Another pattern documented in the 1977 Environmental Fund chart concerns literacy rates. These rates for individual countries have been collected from various sources (UNESCO, US Department of State, CIA and others), and they are likely to be vagariously defined and of questionable accuracy. Even so, it is interesting to plot the literacy rates against the population growth rates for the 157 countries included in the chart. This is done in Fig. 1. The black squares are regional averages (Africa, 22% literacy and 2.8% population growth rate; Asia, 49 and 2.4; North America, 99 and 0.8; Latin America, 65 and 2.8; Europe, 96 and 0.6; USSR, 98 and 1.0; Oceania, 84 and 1.8), and the large star is the global average (59% literacy and 2.1% growth rate).

No simple message emerges from Fig. 1. It does suggest that low population growth (below 1% say) is correlated with high literacy, but even here Portugal

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

Region	Population in mid-1950 (millions)	Population in mid-1977 (millions)	Average growth rate (% p.a.)	1977 growth rate (% p.a.)
Africa	219	451	2.7	2.8
Asia	1,409	2,506	2.1	2.4
North America	166	247	1.5	0.8
Latin America	164	342	2.7	2.8
Europe	392	479	0.7	0.6
USSR	180	259	1.3	1.0
Oceania	12	22	2.2	1.8

Fig. 1 Percentage literacy is plotted against annual population growth rate for 157 countries (a few of the crosses represent two countries). The solid squares are regional averages, as described in the text; the large star is the global average.

(-0.4% population growth with 65% literacy) is an exception. At the other end, although there are a lot of countries with population growth rates in the range

2-4% and literacy rates below 30%, the figure does not support any unambiguous correlation between high population growth and low literacy. □

New ways to look at X inactivation

from M. Bobrow

MAMMALIAN embryogenesis is very sensitive to alterations in the 'balance' of genetic material. Additions or losses of whole chromosomes usually produce severe phenotypic derangements. In this context, the sex chromosomes are somewhat of an anomaly. The Y chromosome contains little if any genetic information other than that directly relevant to inducing testicular differentiation of the primitive gonad. The X chromosome is large and contains at least several hundred gene loci having nothing to do with sex differentiation. However, the female develops normally with two X chromosomes, while the male manages at least as well on only one.

The crucial mechanism behind this phenomenon is a regulatory system which allows only one X chromosome to remain active in a diploid cell. First proposed in 1961 (Lyon *Nature* **190**, 372) the 'Lyon hypothesis' has been proven

substantively correct, but details of the process are still obscure (well reviewed by Gartler & Andina *Adv. hum. Genet.* **7**, 99; 1976).

The basic hypothesis states that, at some stage during early embryogenesis, all X chromosomes bar one are inactivated and are no longer available for transcription. Which X remains active in any given cell is randomly determined. The process involves a whole chromosome rather than individual genes, and is accompanied by physical changes in the chromosome—it is visible as a highly condensed body during interphase (the Barr body) and the timing of its DNA synthesis is shifted to a later stage of the cell cycle than its active homologue. Whatever the nature of the inactivation process it is heritable, so that descendants of a given cell form a clone. Every normal female is thus a somatic cell mosaic, some cells having an active paternally-derived X, and others an active maternal X. The growth of knowledge concerning biochemical markers of X chromosome activity, and the powerful new techniques for manipulating the genetic constitution

of mouse embryos (by forming chimaeras, for example), has led to a recent wave of interest in the timing, extent and randomness of X inactivation.

Cytological evidence of X inactivation first appears in the early blastula of the mouse (± 40 cell stage). Functional inactivation was studied in a most elegant experiment: single cells from 3.5-4.5 d blastocysts were injected into host blastocysts, and formed chimaeric mice displaying patches of activity of both X chromosomes of the injected cell—implying that cell transfer had preceded X inactivation. (Gardner & Lyon *Nature* **231**, 385; 1971) Studies of 'patch size' of X-linked markers in adult female heterozygotes lead to rough estimates of 10-60 cells present in the embryo at the time of X inactivation.

Another approach to the timing of X inactivation is the biochemical analysis of X-linked gene products in the early embryo. Before inactivation, XX embryos should produce twice as much gene product as their brothers, which would lead to a bimodal distribution of gene activity. An obvious pitfall is that unimodal distributions of enzyme activity in very early embryos may reflect pre-fertilisation oocyte transcription.

A recent example of this approach (*Nature* **270**, 599; 1977) is the study of Monk and Kathuria, who analysed HGPRT activity in single mouse embryos. They found a unimodal distribution of activity in 8-cell embryos and in pre-implantation blastocysts—at which stage the embryonic genome is certainly active. There is evidence of embryonic synthesis of HGPRT from a very early stage of embryogenesis, and this finding would therefore suggest that X inactivation has occurred well before implantation; earlier than suggested by the other approaches. This discrepancy could be due to methodological difficulties in one or more of the techniques; inactivation occurring at different times in different embryonic cells; or to inactivation not affecting the whole chromosome simultaneously. An intriguing speculation would be that regions of the chromosome are inactivated as their transcriptional products are required in the differentiating embryo.

The concept of random inactivation seems to be generally valid, but three major exceptions have been discovered. X/autosome translocations and structurally abnormal X chromosomes in both man and mouse show preferential inactivation of one or other X chromosome—but these situations have only been studied in adult animals and may represent post-inactivation cell selection. Information on inactivation in early embryos with X/autosome translocations would be most interesting. In marsupials, the paternal X chromosome is preferentially inactivated and a similar situation pertains in the extra-embryonic membranes of rodents (refs in Gartler &

Martin Bobrow is a member of MRC external scientific staff, working in the Oxford University Genetics Laboratory and the Oxfordshire Area Health Authority's Department of Medical Genetics.

Andina *op. cit.*). This seems to imply some form of chromosome 'imprinting' to mark the paternal X chromosome, and it has been suggested that this is a fundamental and primitive form of X inactivation, from which some cells of the eutherian embryo have learned to escape. That imprinting is not a necessary prerequisite of X inactivation has been finally demonstrated by Kaufman, Guc-Cubriilo and Lyon (this issue of *Nature*, page 547) who have provided cytological evidence of X inactivation in the absence of any paternal genetic contribution, using parthenogenetic embryos created by suppression of polar body formation.

Despite a variety of interesting suggestions on mechanisms for permanently modifying DNA bases or structural configuration (see refs in Gartler &

Andina *op. cit.*) virtually nothing is known of the biochemical or biophysical basis of X inactivation. This, and many other aspects of this fundamental process of mammalian genetic regulation, may become amenable to investigation following the exciting discovery of Martin *et al.* (*Nature*, 271, 329; 1978). These workers have demonstrated that mouse teratocarcinoma cell lines maintained *in vitro* show biochemical evidence of X inactivation if they are grown under conditions which allow them to initiate morphological differentiation. If this experimental model turns out to be as useful as it promises on first sight, our understanding of the process of X inactivation, and of whole-chromosome genetic regulatory mechanisms, may advance rapidly over the next few years. □

Smoothing primaeval chaos

from Paul Davies

THERE are two conflicting philosophies about the nature of the Universe. The first, which meshes well with traditional religious beliefs, is that the world we live in is a very special sort of place, elaborately constructed to be just the way it is and no other. The second holds that there is nothing really remarkable about the Universe, given the laws of physics. According to the latter, the world is a pretty random sort of place. The nexus of this controversy focuses on the creation event—the so-called big bang—which apparently took place about 15 billion years ago and represents the origin of all space, time and matter. Assuming the reality of this universal genesis, the question naturally arises as to the precise condition in which the Universe was created. Some cosmologists contend that it began in a highly special and extremely improbable condition, others that it started out as though God had chosen the world randomly from all possible alternatives.

To defend the second philosophy, it is necessary to demonstrate that there exists a very wide range of initial conditions that would cause the Universe to subsequently evolve into something closely similar to what we observe today. Another way of expressing this is to say that our basic world structure is stable against random changes in its original state: that almost any sort of big bang would have led inevitably to a Universe of the type we have.

In the past few years a lively debate

has arisen around this question, as our understanding of the primaeval cosmos improves, both through astronomical discovery and theoretical modelling. The central observational fact is that, on an extragalactic scale, the Universe appears to be very uniform and regular, both as regards the distribution of matter in space and the systematic pattern of galactic recession which reveals the overall expansion of the cosmos. The great mystery is: why is the Universe so orderly? Was it simply created in this remarkably uniform condition, or has it contrived to evolve order out of primaeval chaos? A further twist to the problem is that without some degree of irregularity the galaxies themselves would not have formed. Galaxies arose because certain regions of the primaeval gases erupting from the big bang were slightly denser than others, and the locally enhanced gravity associated with this clumping proceeded to trap the surrounding material and prevent it from dispersing under the action of the universal cosmological expansion. In this way, initially rather tenuous irregularities inexorably grew in size and contrast until they became the isolated entities that we now observe.

Several years ago intensive investigations began into the fate of a cosmos which starts out with a large amount of turbulence. Several mechanisms exist which would operate to smooth out the primaeval turbulence. For example, fluid viscosity can damp away chaotic motions and restore orderly flow in many everyday systems. In a cosmological context, the viscosity of

neutrinos (elusive subatomic particles) was suggested by the American cosmologist Charles Misner as a cause of viscous damping operating at about 1 second after the big bang, when the Universe had a temperature of 10 billion degrees. Other damping processes have since been discussed; quantum particle production around 10^{-23} s, graviton collisions at 10^{-20} s, hadron collisions at 10^{-8} s, microscopic black hole production, and so on. All these processes operate to reduce the turbulent chaos and establish a more orderly and regular arrangement of matter.

On the face of it, one could well suppose that, through these many mechanisms, even a highly irregular primaeval cosmos would soon convert into something like the present condition. The snag is that, according to the second law of thermodynamics, the establishment of order out of chaos has to be paid for by an increase in total entropy, most of which appears as heat energy. The heat of the primaeval Universe can still be detected as the celebrated cosmic background thermal radiation, which provides us with a measure of the entropy of the Universe. Although the temperature of this radiation is now very low (about 3 K), it still represents a vast amount of entropy per atom of matter.

In a recent paper (*Mon. Not. R. Astr. Soc.* 181, 719; 1977) John Barrow of Oxford University and Richard Matzner of the University of Texas at Austin have re-examined the relationship between the cosmic entropy and the primaeval turbulence. They point out that although the entropy is large (indicating that a definite amount of dissipation occurred at some stage in the past) it is obviously still finite, and can be used to provide an upper limit on the amount of primaeval disorder. They argue as follows: observations of the thermal background radiation and studies of nuclear processes in the primaeval matter indicate that the Universe was highly isotropic (regular in all directions) as early as a few minutes after the creation event, so any initial anisotropy must have been dissipated before that time, and converted into heat radiation. Now the energy of heat radiation is greater at earlier moments, as one probes closer to the initial creation event, because the Universe is more compressed and so the temperature is higher. Similarly, the energy of the anisotropy turbulence also grows as one approaches the beginning. What Barrow and Matzner point out is that the anisotropy energy grows much more rapidly than the heat energy. The crucial consequence of this observation is that the earlier the anisotropy was dissipated, the

Paul Davies is a lecturer in the Department of Mathematics, Kings College, London.

greater the heat (that is, entropy) it would have produced. For example, if dissipation occurred as early as the so-called Planck era (10^{-43} s) when quantum gravity effects were important, then even a minute amount of initial anisotropy would have produced too much entropy.

Without a detailed understanding of the dissipative mechanisms in the very early stages, it is impossible to place precise numerical constraints on the permitted degree of primaeval turbulence, but the authors conclude on general grounds that an initially highly chaotic cosmology can be ruled out. There is still the problem of accounting for the existence of galaxies in this quieter scenario, a phenomenon about which only rudimentary understanding has been gained.

If Barrow and Matzner's ideas continue to hold for more elaborate models of the big bang, it seems that we shall inevitably be obliged to face the mystery that the Universe has been created in a remarkably orderly and highly special state after all. One possible approach to this mystery is through the anthropocentric—that if the cosmos were not so regular we could not be here to know about it. A highly turbulent big bang would overproduce entropy and the cosmic background radiation would then be too hot for life to evolve until it had cooled below, say, the boiling point of water. But the temperature of this radiation takes billions of years to diminish appreciably, and if it were substantially hotter than now then the stars would have burnt out before conditions became cool enough for life to form. Without stars such as the Sun there would be no life anyway. This is not, of course, an explanation for the orderly Universe, but it provides an intriguing comment on how lucky we are that the big bang was so well-behaved. □

Red deer or takahe?

from Peter D. Moore

THE conservation of a species normally demands an active management of its habitat in order to increase its carrying capacity for that particular species. Where a species requires a habitat in its early stages of succession, this may mean extensive and frequent modifications of the habitat to prevent its maturation. Generally the amount of management effort declines in situations requiring more advanced successional stages, and for climax ecosystems the major problems are often ones of

prevention of destruction of the habitat, or the control of exotic, invasive predatory or competitor organisms. Experimentation, based upon sound and detailed ecological survey and rational extrapolation, is often necessary before the best available management techniques can be devised and implemented.

Such an experimental approach to conservation is most hazardous where one is dealing with an organism on the brink of extinction. Here one cannot afford to make mistakes. Take, for example, the takahe (*Notornis mantelli*), a flightless gallinule endemic to New Zealand. Subfossil remains of the bird suggest that it once had a fairly extensive range in the south-western tip of the South Island of New Zealand, but the European settlers of the nineteenth century found few specimens and during the first part of this century it was considered extinct. Then, in 1948, it was dramatically rediscovered in the high, alpine and sub-alpine tussock grassland of the Murchison Mountains. It is now known to occur in an area of less than 1,000 km² in these mountains and its population in some parts of this area may still be declining.

Obviously, in such a situation, considerable information is required concerning the environmental requirements of the takahe, before management can be applied. One adverse influence in the area may be the introduced red deer (*Cervus elephas*). Questions such as whether these two species are in competition and whether the deer are modifying the habitat in a manner unfavourable to the takahe, need to be answered.

Mills and Mark (*J. Anim. Ecol.* 46, 939; 1977) have attempted to provide the information needed to answer these questions. They studied a series of 10 m × 5 m plots in tussock grassland within takahe territory which were situated among the four major dominant tussock-forming plants, *Chionochloa pallens*, *C. flavescens*, *C. teretifolia* and *C. crassiuscula*. Usage of the plots was assessed by counting the droppings within them, which can be expected to reflect the amount of time spent by takahe in each. Damage to plants (the bird is herbivorous) could also be estimated directly since tussock tillers are pulled off, the base eaten and the remainder discarded in a pile.

This type of study has led Mills and Mark to conclude that the preferred food of the takahe consists of *C. pallens* and *C. flavescens*, their relative proportions varying seasonally. Plots dominated by these two species were

Peter D. Moore is a senior lecturer in the Department of Plant Sciences, King's College, London.

also richer in deer faeces, particularly *C. flavescens*. Chemical analyses of the tillers of four *Chionochloa* species showed that the preferred two species exceeded the others in their concentration of N, P, K, Ca, Mg and soluble sugars (P and K statistically significant). This was not the case for S, Na and starch content. *C. teretifolia* was the species with the lowest overall food value and this species was not recorded as eaten by takahe in the study plots.

From this study it is evident that the two species, *C. pallens* and *C. flavescens*, are more nutritious and are preferred as food sources by the takahe. The red deer, however, has similar food preferences and this fact, together with the limited abundance of the two plant species (20% and 10% cover respectively) indicates that competition for food may be taking place between the two species. Analyses of individual tussocks which had been selected for grazing suggest that both takahe and red deer selected plants rich in phosphorus for their attention. Overall, the red deer had a more varied diet, including more dicot species, but the coincidence of their preference for phosphorus-rich *C. flavescens* tussocks confirms an overlap of niche and hence a competitive interaction. Severe competition, however, may be avoided by the fact that deer take the leaf blades whereas takahe take the basal sheaths.

The impact of the competitive interaction is likely to be most severe when some other factor, such as prolonged snow cover in a severe winter, causes harder grazing by the deer and consequent damage to the structure and composition of the alpine grasslands. Under such conditions, of course, the first plants to suffer will be those with the highest phosphorus content, thus depriving the takahe of their nutrient resource.

The New Zealand Forest Service is currently conducting deer population control operations in the area and the work of Mills and Mark suggests that this could have beneficial effects not only for forestry but also for the alpine grasslands and the takahe. For this endangered species, the removal of red deer is likely to do nothing but good.

Order in amorphous polymers

from Paul Calvert

THE problem of whether there is long range order in liquid and glassy polymers has long been troubling polymer science. The 1975 Shrivernham Meeting on Polymer Physics followed closely after a symposium on 'Physical struc-

ture of the amorphous solid state' (*J. macromolec. Sci.* **B12**, 1; 1976) and it seemed that the question was settled; there was no long range order. By the 1977 Shrivenham Meeting the problem had returned, as intractable as ever.

The description of order in liquids and glasses has always been difficult. Bernal's model of dense random packing of liquids was derived by filling a balloon with ball bearings, kicking it round the laboratory, then fixing the structure by pouring in paint so that it could be disassembled and analysed. Regrettably a similar experiment for chain molecules has not been done.

Electron micrographs of thin films of amorphous polymers show 20–50 Å nodules which G. S. Yeh (*J. macromolec. Sci.* **B6**, 451, 465; 1972) claimed to be due to locally ordered regions surrounded by less ordered material. Many microscopists believe these nodules to be artefacts of beam damage, and at the 1975 symposium this straw man was soundly beaten. Small angle X-ray scattering showed unambiguously that there are no significant density fluctuations and small angle neutron scattering demonstrated that the molecules had the same overall radius of gyration as in θ (ideal)-solution suggesting that there could be no ordering. However, semicrystalline polymers have since been found also to have this random coil radius of gyration, so this result must be compatible with order. Yeh has modified his ideas to suggest that the observed blobs are a diffraction effect from regions where the chains are locally parallel. Similar to this is the Pechold meander model (Pechold & Blasenbrey *Koll. Zeit.* **241**, 995; 1970) in which the structure consists of curved, randomly packed bundles of parallel chains. At Shrivenham 1977 it was shown that by folding the bundles correctly a suitable molecular radius of gyration could be produced. There is really no such explicit model of a structure with long range order.

To complement the shortage of models there is also a shortage of methods. Using X-ray diffraction data Warren and Mozzi (*J. appl. Crystallogr.* **2**, 164; 1969) produced a convincing structure for glassy silica based on misalignments of adjacent SiO_4 tetrahedra, but polymers contain more atoms per repeat unit and there is just not enough information in the few broad diffraction peaks that are observed. Wecker, Davidson and Cohen (*J. Materials Sci.* **7**, 1249; 1972) found that the structure in amorphous isotactic polystyrene closely resembled the crystalline state, implying that the chains adopted the same helical structure in each case, and the main change was in the relative arrangement of the helices. Windle and

Lovell (*Polymer* **17**, 488; 1976) have been squeezing more information out of these systems by looking at X-ray diffraction of oriented polymers (this ploy of using fibre patterns is how most crystalline polymer structures have been solved). The spacings of reflections parallel to the chain axes allow the helical conformations to be determined. However, the samples are not really sufficiently oriented, so that it is necessary to sharpen the patterns by analytical methods which might introduce spurious peaks. The results reported at Shrivenham 1977 confirm Wecker's isotactic polystyrene results, propose a predominantly ttgg (t, trans; g, gauche) helix with some tttt for commercial atactic polystyrene which is 70% syndiotactic and suggest a ttg helix for polymethylmethacrylate (Perspex). A rule due to Natta for polymer crystal structures is that intermolecular interactions do not usually distort the chain from the minimum energy conformation of an isolated chain. These results suggest that the predominant helix in amorphous polymers is that found in the crystal structure, so that a similar rule could be proposed that the distribution of conformations in liquid, glass and θ -solvent is the same as that calculated from intramolecular potentials alone. But this still says nothing about how the chains are packed together.

Markova and coworkers claim to have detected regular intermolecular spacings indicative of ordered regions of at least 50 Å by electron diffraction (*J. Polym. Sci. C* **42**, 671; 1973) though

their data analysis has been criticised (Voigt-Martin & Mijchhoff *J. appl. Phys.* **46**, 1165; 1975). At Shrivenham 1977 Longman and Wignall described the level of order in polyethylene as being similar to that in liquid paraffins. Since, however, it is impossible to find two groups in this field who accept each other's data analysis, it is hard to know how firm these conclusions are.

In principle infrared spectroscopy or NMR ought to be able to detect chain conformations associated with kinks in the helix where the chain changes direction, but I am not aware of any such quantitative measurements. Light scattering can detect regions of local orientational order, thus Brillouin scattering and depolarised Rayleigh scattering both support Longman and Wignall's conclusion that polyethylene is no more ordered than paraffin chains of 20–30 atoms (Patterson *et al. Macromolecules* **10**, 667, 737; 1977; *J. macromolec. Sci.* **B12**, 61; 1976.)

If, then, we ask whether chains in the amorphous state adopt the same conformations as in θ -solvent the answer so far seems to be yes. On this basis the length of the straight sections of chain will depend on chain stiffness, in line with the observation that stiff molecules such as polytetrafluoroethylene and poly-4-methyl pentene show particularly sharp X-ray diffraction peaks in the liquid state, implying increased order. We must now ask if it is possible to pack the molecules to the required density without them lying parallel, and so far there is really no answer to this. □

Handedness of atoms and parity non-conservation

G. Feinberg*

Experiments to test the existence of parity non-conserving interactions in atoms are described. Such experiments have been done in heavy atoms, but their theoretical interpretation is difficult. Prospective experiments in hydrogen and deuterium should clarify the situation, and determine which unified gauge theory can describe weak and electromagnetic interactions.

THE phenomenon of handedness, that is, the existence of physical systems that are not identical to their mirror images, is well known for macroscopic systems, such as the human body. It is also well known that some molecules, such as tartaric acid, occur in two forms with opposite handedness, which can be distinguished from each other by their property of rotating the plane of linearly polarised light in opposite directions¹.

The existence of handed molecules has nothing to do with parity non-conservation, that is, with a failure of the complete molecular energy operator to be invariant under space reflection, although it is conceivable that the prevalence of one type in living things on earth is related to such failure². The two types of molecule are both quasi-stable states, and their existence is the consequence of near degeneracies between opposite parity energy levels of a parity conserving electrostatic potential energy³.

If the atomic potential energy contains some small terms that do not conserve parity, then it is possible that in isolated atoms, where such near degeneracies are not found, there may occur a more profound type of handedness, such that the mirror image of an atomic state is not a stable state at all. This would be analogous to the situation for neutrinos: as far as we know, only left-handed neutrinos occur in nature, and the mirror image right-handed neutrinos do not exist⁴.

If any such handedness occurs in atoms, it must be very small⁵. Furthermore, until about 1968 there was little theoretical reason to expect any parity non-conserving terms in the atomic potential energy. But over the past 10 years, the invention of theories that unify weak and electromagnetic interactions⁶, and the apparent success of such theories in describing neutrino scattering, have provided new stimuli to the search for handedness in atoms.

In these unified theories, the interaction energy between electrons and nuclei originates not only from the exchange of photons, but also from the exchange of massive neutral, spin-1 particles. This new interaction energy, unlike that coming from photon exchange, may not be invariant under space reflection, because the spin-1 Z particles that are exchanged, have as their sources both vector and axial vector currents which behave oppositely under space reflection. The potential coming from Z particle exchange is also very short range because of the high mass of the Z particle, and so involves the small probability of finding an electron at the nucleus of the atom. In terms of the electron wave functions the parity non-conserving interaction may be written as

$$H_{PV} = \frac{G_F}{\sqrt{2}} \sum_i \sum_j \left[(C_{1P} \psi_i \gamma_\mu \gamma_5 \psi_i(\gamma^\mu)_{P_j} + C_{1N} \psi_i \gamma_\mu \gamma_5 \psi_i(\gamma^\mu)_{N_j} + C_{2P} \psi_i \gamma_\mu \psi_i(\gamma^\mu \gamma^5)_{P_j} + C_{2N} \psi_i \gamma_\mu \psi_i(\gamma^\mu \gamma^5)_{N_j} \right] \quad (1)$$

In this formula ψ_i are the Dirac wave functions of the electrons in the atom, evaluated at the nucleus, and the sums i, j are carried out over the electrons and the neutrons (N) and protons (P) respectively. The constant G_F is the weak interaction coupling constant ($G_F \approx 10^{-49}$ erg cm⁻³). C_{1P}, C_{1N}, C_{2P} , and C_{2N} are numbers which vary from one unified gauge theory to another, and are the quantities that theorists would most like to find from a study of atomic handedness. In the standard theory of Weinberg and Salam^{6,7} the values of the C_i are given by

$$\begin{aligned} C_{1P} &= \frac{1}{2}(1-4\sin^2\theta) & C_{2P} &= \frac{1}{2}(1-4\sin^2\theta) \\ C_{1N} &= -\frac{1}{2} & C_{2N} &= -\frac{1}{2}(1-4\sin^2\theta) \end{aligned} \quad (2)$$

The quantity $\sin^2\theta$ must be determined from experiment. The neutrino experiments⁸ are fitted by the standard theory with $\sin^2\theta \approx 1/4$. In other unified gauge theories, more complex than the original theory, the values of these constants may be different. Indeed, in one class of theories, there may be little or no parity non-conserving interaction between electrons and nucleons. Therefore, the detection and precise measurement of atomic handedness can provide a crucial test of these forms of the gauge theory.

The terms in H_{PV} will have matrix elements between states of opposite parity. The terms involving C_1 are proportional to the number of protons (Z) and neutrons ($A-Z$) in the nucleus, while those involving C_2 are proportional to the spins of the proton and neutron. We shall see that the latter terms are less important in heavy atoms, and in experiments that are insensitive to the nuclear spin alignment. Because each term involves the electron wave functions at the nucleus, the only states for which the matrix elements are not negligibly small are $S_{1/2}$ and $P_{1/2}$ states. In other states, the Dirac wave functions all vanish at the nucleus. Accordingly, H_{PV} will lead to a parity mixing in $S_{1/2}$ and $P_{1/2}$ single electron states. That is, an $S_{1/2}$ state will actually contain a small admixture of various $P_{1/2}$ states and conversely.

The amount of this admixture, which measures the handedness of the atom, will be given, for a specific $S_{1/2}$ state, by

$$\delta(S, nP) \sim \frac{\langle S_{1/2} | H_{PV} | nP_{1/2} \rangle}{[E_{S_{1/2}} - E_{nP_{1/2}} + (i/2)(\Gamma_{S_{1/2}} - \Gamma_{nP_{1/2}})]^{-1}} \quad (3)$$

where E is the energy of the state, and Γ is its decay width.

This mixing can be calculated straightforwardly for a hydrogen or deuterium atom. It is found that in such atoms by far the largest mixing occurs between $S_{1/2}$ and $P_{1/2}$ states of the same principal quantum number, such as $2S_{1/2}$ and $2P_{1/2}$. This is because the energy difference between these states is abnormally small, given by the Lamb shift, which is of order 10^{-6} eV, compared to several eV for the energy difference between states of different principal quantum number. Because of the presence of the nuclear spin dependent terms in H_{PV} , the mixing depends on which of the

*Department of Physics, Columbia University, New York, New York 10027

Table 1 Calculations and experimental results on optical rotation in bismuth

Wavelength of transition (Å)	Experiment	Theory, ref. 18	Theory, ref. 21	Theory, ref. 20	Theory, ref. 16
8,757 Å	-0.07 ± 0.32 (ref. 14)	-2.3	-1.2	-2.3	-1.6
6,477 Å	$+0.27 \pm 0.47$ (ref. 15)	-3	-1.6		-1.7

The numbers given are for $10^7 \times \text{Im}M(E1)$. Most of the calculations use the value $\sin^2\theta = .35$. Use of the value $\sin^2\theta = 0.25$ will decrease the theoretical values by a factor of about 0.8.

hyperfine states in hydrogen are being mixed. In the case of zero external magnetic field, the mixing can be written as⁹

$$\delta(2S_{1/2}, 2P_{1/2}) = -i\bar{C}(1.2 \times 10^{-11}) \left(1 + \frac{i(\Gamma_{2S_{1/2}} - \Gamma_{2P_{1/2}})}{2(E_{2S_{1/2}} - E_{2P_{1/2}})}\right)^{-1} \quad (4)$$

In this equation

$$\bar{C} = C_{1P}Z + C_{1N}(A-Z) - [F(F+1) - I(I+1) - \frac{3}{4}] / (C_{2P}K_P + C_{2N}K_N) \quad (5)$$

where F is the total angular momentum and I is the nuclear angular momentum. K_P and K_N are 2 and 0 in hydrogen, and both 1 in deuterium. The ratio

$$\frac{\Gamma_{2S_{1/2}} - \Gamma_{2P_{1/2}}}{2(E_{2S_{1/2}} - E_{2P_{1/2}})}$$

is approximately 1/20 in hydrogen or deuterium.

It can be seen from equation (4) that if the C_i values are numbers of order 1, as expected in the Weinberg model from equation (2), then the mixing in neutral hydrogen or deuterium is approximately

The small value of δ is a consequence of the very short range of the weak interactions that generate H_{PV} , in comparison with the size of an atom. This range is approximately 10^{-16} cm, and the probability of finding an electron that close to a nucleon in an atom is very small indeed.

This admixture of opposite parity states will induce a small handedness for a hydrogen atom in a $2S_{1/2}$ or $2P_{1/2}$ state. Because of the very small value of δ it seems difficult to measure this handedness in hydrogen atoms without external fields. Two alternative approaches to the measurement of the atomic handedness predicted by the unified weak interaction theories have therefore been proposed.

Heavy atoms

In atoms with large nuclear charge, such as bismuth, with $Z = 83$, the parity admixture δ can become somewhat larger than in hydrogen, for two reasons. One is that the electron wave functions at the nucleus are much greater in magnitude, as even an S-state valence electron is more likely to be found near a heavy nucleus than is an electron in hydrogen. The other reason is that the terms in H_{PV} involving C_{1P} and C_{1N} are proportional to Z and $(A-Z)$, and so are 100 times or so greater than in hydrogen. On the other hand, the nuclear spin dependent terms involving C_{2P} , C_{2N} are not proportional to Z or $(A-Z)$ and so are presumably 100 times smaller in heavy atoms, and negligible as a first approximation. These enhancement effects in heavy atoms are somewhat counteracted by the fact that the energy differences of opposite parity states of valence electrons of heavy atoms are of order 1 eV, rather than the 10^{-6} eV of the $2S-2P$ splitting in hydrogen. Calculations by Bouchiat and Bouchiat¹⁰ indicate a typical value for the mixing coefficient between individual states of opposite parity in a heavy atom such as Bi, of about 10^{-10} , or 10 times greater than the $2S-2P$ mixing in hydrogen.

Two types of experiment have been attempted to detect the parity mixing in heavy atoms. One type, proposed by Bouchiat and Bouchiat¹⁰, is in progress in Paris¹¹ and at Berkeley¹². It

involves comparing the absorption rates of left-circularly polarised and right-circularly polarised photons by the heavy atoms. If the atoms have a slight handedness, these rates will be different. The difference arises because the absorption can, in the presence of handedness, occur both through magnetic dipole ($M1$) and electric dipole ($E1$) transitions, and these two terms interfere to give a difference in the absorption rates. A situation is chosen in which the $M1$ transition would occur even in the absence of parity mixing whereas the $E1$ transition only occurs because of this mixing. In this situation, the absorption rates of the two types of photons are proportional to

$$R_{\pm} \sim (M_{M1} \pm \delta M_{E1})^2 \quad (6)$$

where δ is the mixing, and M_{M1} , M_{E1} are the matrix elements for the $M1$ transition between the unmixed states, and for the $E1$ transition between the admixed state and the unmixed part of the other state. Actually δM_{E1} must be summed over all states that can be admixed into the original states.

The relative difference in the absorption rates is for small δ

$$\frac{\Delta R}{2R} \equiv \frac{R_+ - R_-}{R_+ + R_-} \sim 2 \frac{M_{E1}}{M_{M1}} \delta \quad (7)$$

Since M_{E1}/M_{M1} is usually large, this difference is much greater than δ itself, and so is capable of measurement. In the actual experiments in progress, there are additional complications involving static electric fields, which are introduced to help amplify the handedness further, and to distinguish it from background effects.

In the other type of experiments, use is made instead of a relation between the difference of absorption rates for the two circular polarisations of photons, and the angle through which the plane of polarisation of linearly polarised light at resonant frequency is rotated upon passing through a medium consisting of bismuth vapour. This relation is given

$$\Delta\theta \sim \frac{\pi N(\omega - \omega_0)}{(\omega - \omega_0)^2 + \frac{1}{4}\Gamma^2} [R_+ + R_-] \text{Re}(R_+ - R_-) \quad (8)$$

In this formula, N is the number density of Bi atoms, l the path length through the vapour, ω the light frequency ω_0 the resonant frequency, and Γ the width of the resonance. The path length l is limited by the absorption, so that l cannot be more than a few times the absorption mean free path so that

$$1/l \approx \frac{N[R_+ + R_-]^2 \Gamma 2\pi}{4[(\omega - \omega_0)^2 + \frac{1}{4}\Gamma^2]} \quad (9)$$

From equation (8) and (9) we get

$$\Delta\theta \sim \frac{\omega - \omega_0}{\Gamma/2} \frac{\text{Re}(R_+ - R_-)}{R_+ + R_-} \quad (10)$$

Therefore a measurement of $\Delta\theta$ determines the same quantity as does $\Delta R/R$ in the other type of experiment. It is apparently easier to measure a small rotation angle than to measure a small change in absorption rate, and so the optical rotation experiments have proceeded more rapidly. Two experiments of this type have already been done¹³⁻¹⁵ with results summarised in Table 1.

In order to interpret these experiments, it is necessary to

Fig. 1 The Breit-Rabi diagram for hydrogen, with $n = 2$.

calculate R_+ , R_- for the atomic transitions involved. The calculation of M_{M1} , or its direct measurement for the transitions of interest, is not difficult. On the other hand, the calculation of M_{E1} presents substantial problems, even if the values of C_{1P} and C_{1N} are specified. This is because in heavy atoms, no single state dominates the mixing as it does in hydrogen. Instead, a large number of opposite parity states have comparable energy differences from a given state, and are therefore mixed into it by H_{PV} with comparable coefficients. In order to obtain an accurate value for M_{E1} , it is necessary to sum over all such states. We can write

$$M_{E1} = \sum_n \langle i | H_{PV} | n \rangle \frac{\langle n | (E1) | f \rangle}{E_i - E_n} + \sum_n \langle i | (E1) | n \rangle \frac{\langle n | H_{PV} | f \rangle}{E_i - E_n} \quad (11)$$

Here $|i\rangle, |f\rangle$ are the initial and final states, E_i, E_f their energies, $|n\rangle$ are a set of intermediate states with opposite parity to $|i\rangle$, and $(E1)$ is the electric dipole operator

$$(E1) = e \sum_j z_j$$

where the sum is over all electrons in the atom.

Two approaches have been used to calculate this sum. In one, proposed by Bouchiat¹ and Bouchiat¹⁰, and applied to Bismuth by Novikov *et al.*¹⁶, the matrix elements of H_{PV} between certain valence electron states are calculated, and the corresponding matrix elements of $(E1)$ are obtained from experiment. This gives a part of the sum involved in equation (11). Corrections to this coming from other excited states are calculated by various approximations. The results agree fairly well with the other method of calculation, described below (Table 1).

In the second approach, used by Henley and Wilets¹⁷ and by Sandars and collaborators¹⁸, the electrostatic interaction between the electrons is replaced by an average central potential, designed to reproduce the observed energy levels of the states. The difference between this central potential and the true electron-electron interaction is treated as a perturbation. This approximation makes it possible to replace the sum over intermediate states in equation (11) by a sum over single particle excitations. Furthermore, by using a technique invented by Sternheimer¹⁹ and others, it is possible to evaluate the sum directly, in terms of the solution to a differential equation.

$$(H_0 - E)|\psi_1\rangle = (E1)|\psi_0\rangle \quad (12)$$

where H_0 contains the approximate central field, and $|\psi_0\rangle$ is an eigenstate of H_0 with energy E . This is a single particle equation. Once it is solved, $M(E1)$ can be expressed as

$$M(E1) = \langle \psi_{1i} | H_{PV} | f \rangle + i \langle \psi_{1f} | H_{PV} | i \rangle \quad (13)$$

These expressions now include a sum over all excited single electron states, discrete and continuum. The results of these calculations are presented in Table 1. They can be seen to agree fairly well with each other, and with the results of the other approach.

However, there are various corrections to these results that must be considered, involving the effect of the residual interaction, which is the difference between the true electron-electron interaction and the approximate central potential. The effects of this residual interaction have been considered in two recent papers^{20,21}. Henley *et al.*²⁰ analysed the effect of the residual interaction on configuration mixing of the valence electron states, and found it to be small, of the order of a few per cent in Bi.

The contribution of the residual interaction to excitation of core electrons has been analysed by Loving and Sandars²¹, and found to be quite large, and opposite in sign to the contribution of equation (11). The discovery of this new contribution leaves the prediction of the standard gauge theory for the Bi optical rotation measurements somewhat in doubt. Loving and Sandars believe they have isolated and correctly estimated the main effects of the residual interaction, giving the overall result quoted in Table 1. If they are correct in this belief, there remains a substantial disagreement between the standard model and experiment. Further calculations as well as experiments using other heavy atoms will be needed to clarify this point.

Experiments in hydrogen and deuterium

Partly because of the difficulty of making accurate calculations for heavy atoms, and partly because the heavy atom experiments are relatively insensitive to C_{2P} , C_{2N} , several experimental groups have attempted to detect a handedness of hydrogen and deuterium atoms. In such atoms, the atomic physics is quite simple, and if an effect is detected, it can easily be analysed theoretically.

The expected amount of handedness in these atoms given by equations (4) and (5) is quite small, and it must be enhanced in order to be detected. One way to do this is to use external magnetic fields to decrease the energy difference between $2S_{1/2}$ and $2P_{1/2}$ in certain hyperfine states^{22,23}. There are several values of the external magnetic field in the neighbourhood of 10^3 gauss at which level crossings occur between these states (Fig. 1). At such level crossings, the real part of the energy denominator in equation (3) vanishes, leaving only the imaginary part, which we have seen is only $1/20$ as great. This means that δ will be 20 times greater than at zero external field. Furthermore, the states which cross at a specific value of the external magnetic field are specific superpositions of hyperfine states. Because of this, the largest value of δ at a level crossing will involve definite linear combinations of C_1 and C_2 , and these combinations will vary from crossing to crossing. This allows the important prospect of measuring both C_{1P} and C_{2P} by measurements in hydrogen, and also measuring C_{1N} and C_{2N} by further measurements in deuterium.

An example of what is involved is provided by an experiment now under way at the University of Michigan²⁴. In this experiment a beam of hydrogen atoms in a specific $2S_{1/2}$ hyperfine state is introduced into a cavity in which are present static magnetic and electric fields, as well as a microwave frequency electric field. The static magnetic field is approximately 550 gauss, at which value there is a level crossing between one of the $2S_{1/2}$ hyperfine states and a $2P_{1/2}$ hyperfine state. The microwave electric field is chosen at a frequency to induce transitions between the initial state and the crossed level. The transition could not, however, occur in the absence of parity mixing because it would be $M1$, and not inducible by the microwave electric field.

It does occur in the actual setup by two distinct paths. The external static electric field can mix $2S_{1/2}$ and $2P_{1/2}$, thus allowing an $E1$ transition from $2S_{1/2}$ to $2P_{1/2}$ by the microwave field. This path involves no parity violation. Alternatively, the $2S_{1/2}$ – $2P_{1/2}$ mixing can occur through H_{PV} , followed by the same $E1$ transition. The transition rate involves an interference between these two paths, and takes the form²⁴, for the specific conditions of the Michigan experiment,

$$R = R_0[1 \pm 2.5 \times 10^{-6} C_{2P}]$$

where R_0 is the rate in the absence of H_{PV} . The \pm sign occurs for different relative orientations of the various electric and magnetic fields. Therefore, if C_{2P} is a number of order 1, as suggested by equation (2), the transition rate will vary by about 1 p.p.m. as the fields are reversed. The experimenters believe that they can detect this small variation in a reasonable amount of running time. Similar experiments are being carried out at Yale University and at the University of Washington. In each case it is expected that the experiments can be done in deuterium as well as hydrogen. The Yale experiment will be sensitive to a different combination of C_1 and C_2 . The successful completion of these experiments will then give the values of each of the four constants that determine H_{PV} .

If further calculations and experiments in heavy atoms and in H and D confirm the Bi results, it will be necessary to modify the theory leading to equations (1) and (2). A number of proposals along this line already exist^{25,26}. Some of these new models

predict that C_{1P} , C_{1N} both vanish, but C_{2P} , C_{2N} do not²⁵. These models lead to greatly decreased effects in heavy atoms but results similar to the standard model in H and D. In other models all four of the C_i are very small or zero²⁶, and therefore predict diminished parity violation effects everywhere. The H and D experiments will obviously be very useful in distinguishing between these models. Some results are expected within the next year.

Silicalite, a new hydrophobic crystalline silica molecular sieve

A new polymorph of SiO_2 (silicalite, refractive index 1.39, density 1.76 g cm^{-3}) has a novel topologic type of tetrahedral framework. This encloses a three-dimensional system of intersecting channels defined by 10-rings wide enough to adsorb molecules up to 0.6 nm diameter. Silicalite is hydrophobic and organophilic, and selectively adsorbs organic molecules over water.

A MAJOR scientific and technological achievement since 1949 has been the discovery and development of synthetic crystalline, aluminosilicate zeolites as molecular sieve adsorbents and catalysts. We now report the synthesis, crystal structure, and properties of silicalite, a new microporous crystalline silica with remarkable sieve properties. Unlike aluminosilicate zeolites which are hydrophilic, silicalite is hydrophobic and organophilic, and selectively adsorbs organic molecules in the presence of water.

The crystal structure is a new topologic type of tetrahedral framework, which contains a large fraction of five-membered

rings of silicon–oxygen tetrahedra. The framework outlines a three-dimensional system of intersecting channels defined by 10-rings of oxygen ions in all three directions. Organic quaternary ammonium ions which occupy the channels in the precursor obtained by hydrothermal synthesis, are removed by heating to yield silicalite. The resulting void occupies about 33% of the crystal volume, and the three-dimensional channel is wide enough to adsorb molecules up to about 6 Å in diameter. Silicalite can be heated to near 1,300 °C where it degrades to a glass.

Synthesis

The silicalite precursor is crystallised hydrothermally in a closed system containing alkylammonium cations (for example, tetrapropylammonium), hydroxyl ions, and a reactive form of silica at 100–200 °C. The organic-containing precursor crystals have a typical empirical composition $(\text{TPA})_2\text{O} \cdot 48\text{SiO}_2 \cdot \text{H}_2\text{O}$, mean refractive index 1.48, and measured density 1.99 g cm^{-3} . The organic cation is larger than the pore and therefore must be removed by chemical or thermal decomposition (usually calcination in air at 500–600 °C) to yield the microporous silicalite

crystals (mean refractive index 1.39, density 1.76 g cm^{-3}). As the silica framework is electrically neutral, the organic ion is apparently occluded with hydroxyl ions to maintain charge balance, as indicated by infrared spectroscopy. The unit cell composition for the precursor crystals can be expressed as $[\text{4TPAOH} \cdot 96\text{SiO}_2]$. Unlike aluminium-containing zeolites, silicalite has no cation exchange properties.

The crystallisation mechanism of the precursor seems to involve silica clathration of the hydrophobic organic cation analogous to the formation of crystalline water clathrates of alkylammonium salts^{1,2}. Thus the silica tetrahedra assemble into a framework in place of the hydrogen-bonded water 'lattice' of the water clathrate, and surround the hydrophobic organic guest molecules. The alkylammonium ion seems to enhance the solubility of silica in water in a manner reminiscent of the 'structure-breaking' or 'cluster' forming properties of these same ions in aqueous solution³. Indeed, the alkylammonium ion further links the chemistry and structure of water and silica, and seems to translate the structural chemistry of water below room temperature to silica near 200°C .

Crystal structure

Precursor crystals are typically $20 \times 20 \times 70 \mu\text{m}$ elongated along c , and commonly occur as interpenetrant twins on the (110) plane. Crystals calcined to 600°C over 2 d have unit-cell edges a , 20.06; b , 19.80; c , 13.36 Å. The systematic absences ($hk0$, $h = 2n+1$; $0k1$, $k+1 = 2n+1$) indicate space group Pnma or $\text{Pn}2_1\text{a}$. Although the symmetry is apparently orthorhombic, weak diffractions may result from either lower symmetry or intergrowth of a second phase. From 8,297 diffraction intensities collected with monochromatised $\text{CuK}\alpha$ radiation out to 2θ 110° with a Picker FACS-1 diffractometer, 3,542 unique diffractions were obtained with 764 above background (3σ). The crystal was twinned, and overlap of diffractions was corrected for the 90:10 ratio of the twin volumes.

Combination of direct methods (MULTAN program) and model building yielded the structure in $\text{Pn}2_1\text{a}$ (Table 1). The 96 tetrahedra per unit cell form a 4-connected framework with a system of intersecting channels (Fig. 1) composed of near-circular zig-zag channels along a (free cross-section 5.4 ± 0.2 Å) cross-linked by elliptical, straight channels along b (free cross-section $5.7\text{--}5.8 \times 5.1\text{--}5.2$ Å). Both channels are defined by 10-rings. The calculated free cross-section assumes that oxygen ions have a radius of 1.3 Å, and depends slightly on the choice of diametrically-opposing oxygens. The channel system same topology as that reported for a 'shape-selective' has the zeolite⁴, but structural details were not given.

Figure 2A is a photograph down the b axis of a model constructed from tetrahedral stars and plastic linkages. Figure

Fig. 1 Idealised channel system in silicalite. To avoid possible confusion caused by the perspective, the dimensions of the channels along c are shown at upper centre.

3A is a topological drawing showing how the framework can be constructed from pairs of tetrahedra, 4-rings and corrugated bands of 6-rings all cross-linked by 5-rings and occasional 6-rings. Figure 3B shows the a -axis projection. The corrugated bands of 6-rings are seen end-on, and each 4-ring lies between

Values in parentheses following the values for the atom parameters are the error values. The temperature factor was fixed at 1.0 for the silicon atoms and 2.5 for the oxygen atoms.

Fig. 2 A, Framework viewed down *b*; B, Secondary building unit of structure. Twelve tetrahedra linked into five 5-rings and one 6-ring.

two linked pairs. Particularly interesting is the high percentage of 5-rings, a feature shared with the zeolites dachiardite, mordenite, ferrierite and epistilbite. Two other polymorphs of silica, coesite and melanophlogite, also contain 5-rings. The frameworks of the zeolites listed above contain an infinite sheet of linked 6-rings, which might be regarded as a subunit involved in synthesis^{5,6}. Perhaps the corrugated bands of 6-rings may be regarded as a sub-unit in the synthesis of silicalite. Alternatively, the silicalite structure can be assembled from subunits of 12 linked tetrahedra (Fig. 2B).

The structural subunits of silicalite can be assembled into other structure types, as will be described elsewhere. These theoretical frameworks give calculated X-ray powder patterns which do not match the observed X-ray powder pattern for

Fig. 3 Topologic drawings of silicalite structure. A, *b*-axis projection, B, *a*-axis projection. Si atoms lie at the intersections of the lines, and O atoms approximately half-way along the lines. Triple bands of corrugated 6-rings are shown by thick and thin continuous lines. Pairs of tetrahedra and 4-rings occur in projection in (B) as dots and circles and as linked open and filled triangles. In (A) the pairs of tetrahedra and the 4-rings superimpose as linked dots of two sizes. The corners of the unit cell are shown, together with screw diad axes of symmetry.

silicalite. The present structure gives a calculated pattern which fits well with the observed pattern (Fig. 4). Because of the weakness of intensities from the small crystal used for the structure determination, the *R* factor is rather high at 0.16. The twinning of silicalite around {110} may be due to faulting perpendicular to *b* allowing a pseudo-tetragonal framework that permits *a* and *b* axes to interchange giving the appearance of a (110) twin axis. An 'hourglass' zoning is also seen on the (010) and (100) faces. The calculated density is 1.80 g cm⁻³ in good agreement with the measured 1.76 g cm⁻³.

Adsorption

Silicalite is a molecular sieve adsorbent with an adsorption pore size near 6 Å and a saturation adsorption pore volume of 0.19 cm³ g⁻¹ in agreement with the properties expected from its crystal structure. At ambient temperature, it adsorbs molecules as large as benzene (kinetic diameter 5.85 Å) but rejects molecules larger than 6 Å, such as neopentane (kinetic diameter 6.2 Å). Although the pore-size effect can be used in molecular sieving, its most remarkable adsorption property is surface selectivity. In contrast to the extremely high preference of aluminosilicate zeolite surfaces for water (hydrophilic) and other polar molecules, silicalite has a very low selectivity for the adsorption of water and a very high preference for the adsorption of organic molecules smaller than its limiting pore size. This hydrophobic and organophilic selectivity manifests itself in several ways. Adsorption of organic molecules and permanent gases on silicalite occurs by the volume filling of micropores as in zeolite molecular sieves and other microporous adsorbents. The filling of micropores occurs by physical adsorption at low relative pressures, and is characterised by enhancement of the adsorption energy due to increase of dispersion forces resulting from comparable size of the adsorption volume and the adsorbed molecule. This results in a type I, near rectilinear isotherm as illustrated for the gas phase adsorption of *n*-hexane on silicalite (Fig. 5b). Pore filling is essentially complete at a relative pressure of 0.03. In contrast, water does not fill the pores at any relative pressure (Fig. 5a). The adsorbed water volume at a relative pressure near one is about 25% of the saturation pore volume for *n*-hexane. In liquid or gaseous mixtures of organic molecules and water, silicalite selectively adsorbs the organic molecule, and thus is capable of removing organic molecules from organic-water streams.

Most solid surfaces are hydrophilic. Previously known hydrophobic surfaces⁷ include graphitised carbon and microporous and macroporous silicas which have been rendered hydrophobic by removal of the hydrophilic surface hydroxyl groups either by thermal dehydration and dehydroxylation or by chemical modification of the surface to replace the hydroxyl

Table 2 Adsorption volumes in silicalite

Adsorbate	Temperature (°C)	Kinetic diameter (Å)	V_p (cm ³ g ⁻¹)	V_t	Molecules adsorbed per unit cell
H ₂ O	RT	2.65	0.047	0.083	15.1
O ₂	-183	3.46	0.185	0.326	38.0
CH ₃ OH	RT	3.8	0.193	0.340	27.6
<i>n</i> -Butane	RT	4.3	0.190	0.334	10.9
<i>n</i> -Hexane	RT	4.3	0.199	0.350	8.8
SF ₆	RT	5.5	0.167*	—	10.9
C ₆ H ₆	RT	5.85	0.134	0.236	8.7
Neo-pentane	RT	6.2	0.029	0.051	1.4

V_p (cm³ g⁻¹) = Total micropore volume in activated silicalite from saturation capacity, calculated using normal liquid densities at the adsorption temperature. Void fraction, $V_t = V_p$ (cm³ g⁻¹) × d_e (g cm⁻³), where d_e is the measured density 1.76 g cm⁻³. All samples activated by calcination in air at 600 °C followed by vacuum activation (10⁻³ torr). Adsorption measurements all by gravimetric McBain-Bakr balance technique. RT, room temperature.

*At 760 torr.

groups with hydrophobic organic or organosiloxane groups. The water isotherms (Fig. 5A) for Graphon, a dehydrated 'HiSil' silica, and a carbon molecular sieve with a pore size (5.0–5.5 Å) and pore volume (0.20 cm³ g⁻¹) comparable to that of silicalite, suggest that the silicalite surface is similar to or more hydrophobic than the Graphon and dehydrated HiSil surface. The carbon molecular sieve (commercial Pittsburgh activated carbon, Calgon Type MSC-V) is more hydrophilic.

The nature of a hydrophobic adsorbent surface has become understood within the last decade and is reviewed comprehensively in ref. 7. For physical adsorption on an ionic surface, the adsorption interaction energy consists of the sum of dispersion and repulsion energies which originate from non-specific interactions, and electrostatic polarisation, dipole and quadrupole energies which represent specific interactions. For adsorption of water, specific interactions are especially important. In the absence of surface sites which are 'hydrophilic', or of sites for hydrogen bonding, polar or acid-base interactions, the surface becomes nonspecific, homogeneous and hydrophobic. In water, each molecule is hydrogen-bonded to its neighbours (approximately four, as in ice), but in silicalite the narrowness of the channels allows interaction with only about two to three molecules on the average. Because silicalite is electrically neutral, there is no strong interaction with water molecules, and energetically the molecules prefer to remain as a liquid outside the silicalite. What small amount is adsorbed in silicalite is probably associated with the residual hydroxyl groups which persist after thermal removal of the

organic ion in the precursor. The initial isosteric heat of adsorption of water on silicalite is about 6 kcal mol⁻¹, substantially below that of the heat of liquefaction of water (9.7 kcal mol⁻¹), and similar to that reported for Graphon⁷. This requires a high entropy of adsorption, again like Graphon. Low energy and high entropy of adsorption (weak adsorption of highly entropic water) indicate high mobility of the adsorbed water molecule. The strongly hydrophilic nature of aluminosilicate zeolite molecular sieves is due to the presence in the intracrystalline void space of polar groups such as cations and hydroxyl groups, and field gradients generated by the substitution of aluminium for silicon in the tetrahedral framework. Silicalite has no aluminium and no cations in its structure. Chen⁸ has shown a substantial decrease in the amount of water adsorbed on the zeolite mordenite (Zeolon) due to the removal of cations, as well as aluminium from the aluminosilicate framework,

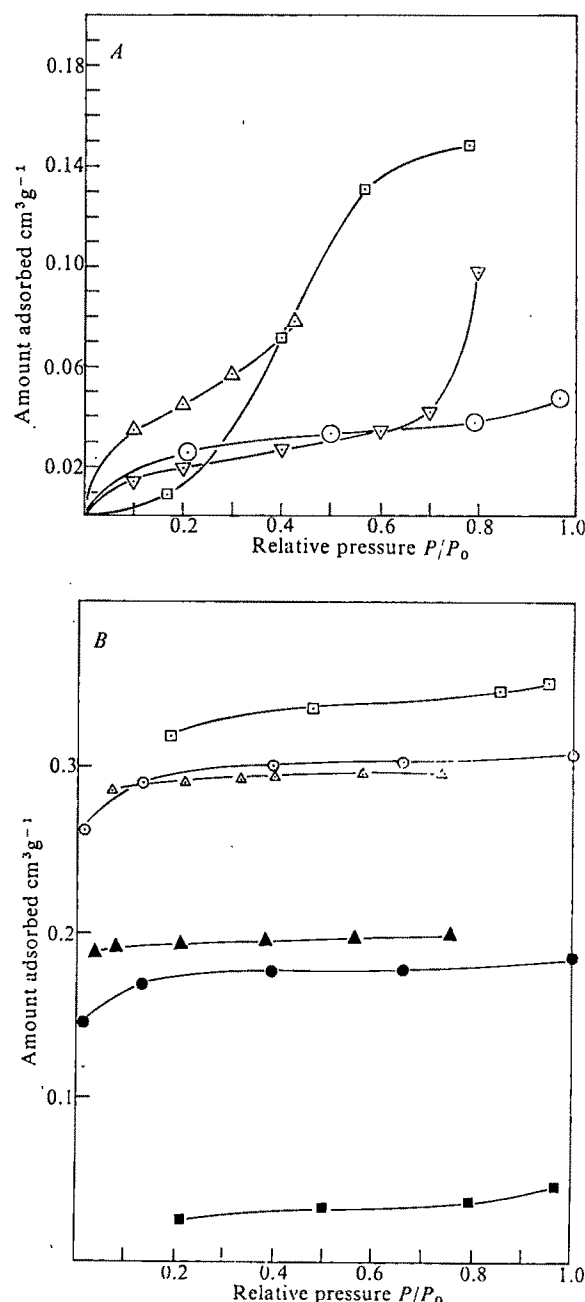

Fig. 5 *A* Water adsorption isotherms on hydrophobic surfaces. □, Carbon molecular sieve; Δ, Graphon; ▽, Hi Sil; ○, silicalite. *B*, Adsorption isotherms on silicalite and NaX zeolite. O₂ at -183 °C, samples activated at 350 °C, 10⁻³ torr; McBain-Bakr gravimetric measurements. □, H₂O on NaX; ○, O₂ on NaX; Δ, *n*-hexane on NaX; ▲, *n*-hexane on silicalite; ●, O₂ on silicalite; ■, H₂O on silicalite.

and described the resulting highly siliceous zeolites as 'hydrophobic'.

Adsorption of *n*-hexane in contrast is highly energetic with isosteric heats of adsorption of 16–18 kcal mol⁻¹ over a wide range of relative pressure. This range is substantially above the heat of liquefaction of *n*-hexane (7.8 kcal mol⁻¹), and similar to the isosteric heat of adsorption of *n*-hexane on the molecular sieve zeolite X, again illustrating the high dispersion energy interactions in crystalline molecular sieves where the adsorption cavities and pores are ≤ 10 Å, commensurate with the size of the adsorbed molecule. Consideration of the volume, size and geometry of the void in the silicalite structure (Figs 1–3) and the number and size of *n*-hexane molecules (8.8 molecules per unit cell and 4.5 Å kinetic diameter) shows that the molecules must be highly oriented in nearly linear strings one molecule thick. The fit of *n*-hexane in the channels is near perfect, and *n*-hexane becomes a low entropy highly ordered liquid in the silicalite lattice. Typical adsorption volumes for a variety of molecules on silicalite are given in Table 2.

Stability

Silicalite possesses a remarkable stability for a 33% porous crystal. It is stable in air to over 1,100 °C, and only slowly converts to an amorphous glass at 1,300 °C. It is stable to most mineral acids but reacts with HF similarly to quartz. X-ray emission measurements of the SiK β band show that the mean Si–O bond energy of silicalite exceeds that of quartz by 0.1 eV,

and is essentially the same as for cristobalite. In contrast, the mean Si–O bond energy in aluminosilicate zeolites is substantially less than for quartz⁹.

Applications

Thus silicalite may offer practical applications in the clean-up of water contaminated with organic compounds. Traces of methanol, propanol, butanol, phenol, 1,4-dioxane, pentane and hexane have been removed from water. The selectivity of silicalite is nearest to that of adsorbent carbons, but it has the advantage of much higher stability to regenerative commercial processes involving thermal, acid, and oxidative conditions.

We thank T. R. Cannan for his assistance in synthesis and adsorption characterisation, and Union Carbide Corporation for permission to publish this article.

Radon emanation on San Andreas Fault

Chi-Yu King

U S Geological Survey, 345 Middlefield Road, Menlo Park, California 94025

Subsurface radon emanation monitored in shallow dry holes along an active segment of the San Andreas fault in central California shows spatially coherent large temporal variations that seem to be correlated with local seismicity.

RADON is constantly emanated from the Earth into its atmosphere, normally in minute amounts. Radon emanation is known to be anomalously large on active faults and to show temporal variations related to changing atmospheric conditions and possibly nearby seismic activities^{1,2}. To check whether it may show premonitory changes useful for earthquake prediction like those reported for the emanation from deep aquifers^{3,4}, the US Geological Survey began on 7 May 1975 to monitor subsurface radon emanation in 20 shallow dry holes along an active 60-km segment of the San Andreas and Calaveras faults in central California (stations 1–20, Fig. 1). Here I present some initial results of this experiment and discuss possible explanations.

We used a simple track etch method^{5–7} that had been developed for uranium exploration to measure radon emanation: a small piece of plastic film (cellulose nitrate) which is sensitive to α radiation is attached to the inside bottom of a plastic cup (9 cm high, 7 cm aperture). The cup is placed upside down at the bottom of a borehole (10 cm in diameter, 0.7 m deep) to expose the film to the soil gas for 1 week, after which it is replaced by a new cup. The air gap in the cup is sufficient to shield the film from all α particles generated in the soil. As radon and its isotopes are gaseous, however, they may move into the cup to emit α particles close enough to leave tracks in the film. The retrieved film is then chemically etched and the enlarged α -particle tracks in the film within an area of nearly 6 mm² are counted under a microscope. The measured track density is then assumed to be proportional to the average radon

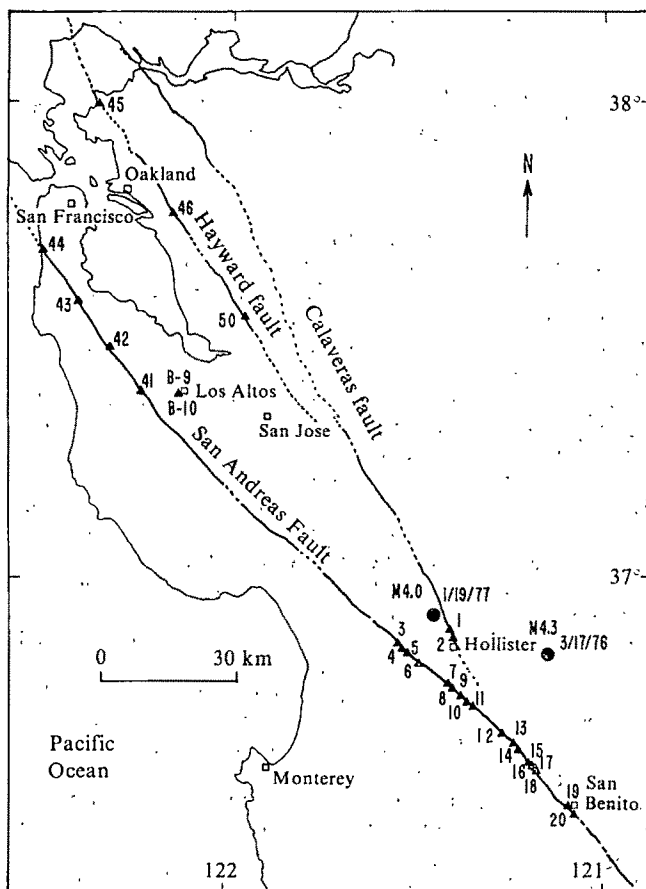

Fig. 1 Location of radon monitoring stations in central California (▲ with station identification numbers) and epicentres of two larger earthquakes (● with magnitudes and dates).

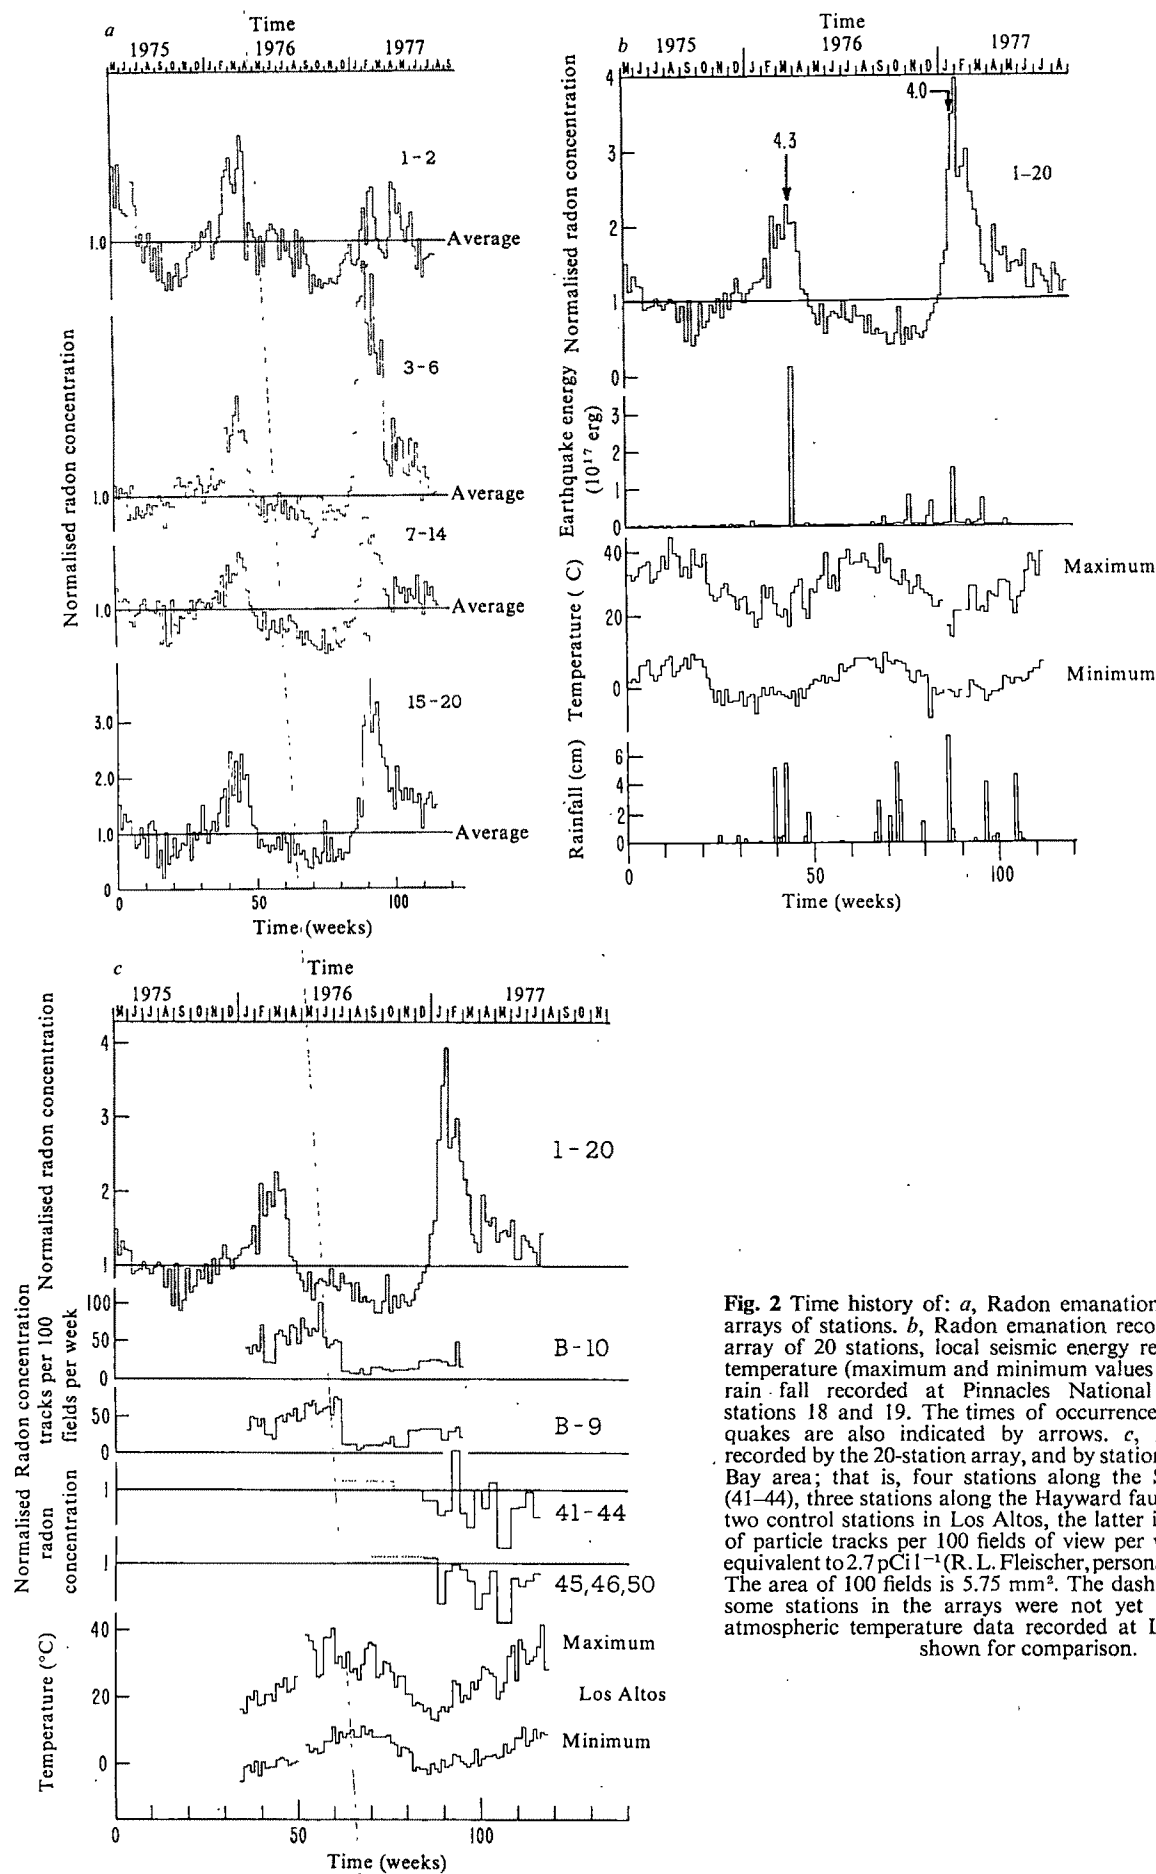

Fig. 2 Time history of: *a*, Radon emanation recorded by four arrays of stations. *b*, Radon emanation recorded by the whole array of 20 stations, local seismic energy release, atmospheric temperature (maximum and minimum values of each week) and rain fall recorded at Pinnacles National Monument near stations 18 and 19. The times of occurrence of the two larger quakes are also indicated by arrows. *c*, Radon emanation recorded by the 20-station array, and by stations in San Francisco Bay area; that is, four stations along the San Andreas fault (41-44), three stations along the Hayward fault (45, 46, 50), and two control stations in Los Altos, the latter in units of number of particle tracks per 100 fields of view per week. Each unit is equivalent to 2.7 pCi l^{-1} (R. L. Fleischer, personal communication). The area of 100 fields is 5.75 mm^2 . The dash lines indicate that some stations in the arrays were not yet in operation. The atmospheric temperature data recorded at Los Altos are also shown for comparison.

concentration of the soil gas in the hole during the period of measurement. In the following, I shall not differentiate between the various contributions to the recorded α radiation by radon and by the isotopes thoron and actinon which have much shorter half lives (55 s and 4 s, respectively) than radon (3.8 d).

The boreholes are supported by plastic pipes 0.8 m long. The upper ends of the pipes are approximately 0.1 m above ground surface and are capped to prevent surface water from flowing into the holes and to reduce possible atmospheric effects. A small amount of moisture was sometimes observed on the retrieved films, especially during the springs for these stations, but it does not seem that the moisture has caused any serious detection problems such as reduced sensitivity, since higher radon emanation was recorded during the springs at these stations. The monitoring sites are located mostly in the fault zones for the purpose of maximising possible tectonic signals, because tectonic strain changes are likely to be amplified in a fault zone due to the mechanical weakness of the zone⁸.

The measured weekly average values of radon concentration of soil gas ranged from 5 to 2,300 pCi l⁻¹. Figure 2a shows radon concentration as a function of time for the 20 stations grouped into four small arrays (stations 1–2 on the Calaveras fault, stations 3–6, 7–14 and 16–20 from north-west to south-east along the San Andreas fault) to improve the signal-to-noise ratio. Data of each array are obtained by first dividing the weekly readings of each station by the average value of the station during the first 40 weeks, and then by summing these 'normalised' values of the same week for all the stations in the array with equal weight.

It is evident from Fig. 2a that the measured radon emanation shows large temporal variations that are spatially coherent over long fault segments (≥ 60 km). The radon variations are not correlated with the relatively small amount of rainfall (Fig. 2b). Also they do not seem to correlate significantly with barometric pressure changes, presumably because of the integrated nature of the measurement, each value representing a weekly average. But because the two prominent peaks in the radon data are separated by nearly a year (46 weeks), one may suspect a seasonal effect, possibly caused by atmospheric heating and cooling of the ground. As shown in Fig. 2b, the correlation between the recorded radon emanation and the atmospheric temperature seems to be exceptionally close. Other observations suggest, however, that this correlation may well be fortuitous. If, for example, the observed temporal radon variations are due mainly to a seasonal effect, one might expect to see fairly similar variations in climatically similar areas, though differences can be caused by different geological conditions at individual sites. Figure 2c shows the radon data recorded by stations that were later installed in the San Francisco Bay area (Fig. 1). These include four stations along a 'locked' segment of the San Andreas fault (41–44), three stations along the Hayward fault (45, 46, 50) and two control stations that are only 3 m apart in Los Altos which is about 8 km off the San Andreas fault. The temperature data recorded at Los Altos are also shown in Fig. 2c for comparison. The radon emanation there apparently varied quite differently, although the temperature variations are similar to those recorded in the 20-station area.

Figure 2b also shows the weekly energy release by earthquakes of magnitude 1.0 and larger within 30 km of the network computed from an energy-magnitude relation given by Richter⁹. The correlation between the radon and the seismicity data seems to be reasonably good. The two largest quakes (magnitude 4.3 and 4.0, respectively), as indicated by arrows in Fig. 2b and solid circles in Fig. 1) occurred near the times when the radon emanation reached its peaks. The emanation began to increase rapidly several weeks before the magnitude 4.3 quake when the smaller quakes did not yet increase in number. This result may indicate that the increase in radon emanation is not due to seismic shaking but may possibly be due to strain build up. In contrast, both radon emanation and seismicity increased more or less concordantly during the second 'anomalous'

Fig. 3 Radon concentration of subsurface soil gas as a function of depth, *a* for a theoretical model (after Clements¹¹); *b*, observed at site 20. The square indicates a long-term average value at the usual monitoring depth of 0.7 m. ●, Indicate the result for an anomalous period (weeks 96–98) and the triangles the result for a nearly normal period (weeks 99–100). The bars indicate 1 σ .

period in which the magnitude 4.0 quake occurred.

From the available data, I suggest that the observed radon variations are more likely to be related to those of seismicity than atmospheric temperature.

If the observed radon variations are indeed mainly earthquake related, what is the responsible mechanism? In view of the fact that radon has a short half life (3.8 d) and moves slowly in the ground¹⁰, it is unlikely that the detected radon comes from earthquake sources several kilometres deep. The anomalously high radon emanation, however, may conceivably be due to an increase in crustal compression that squeezes out the soil gas in the deep reaching fault gouge zone into the atmosphere at an increased rate, as an increased outgassing rate may perturb the vertical subsurface radon concentration profile (radon concentration is known to increase rapidly with depth by about 3 orders of magnitude), such that deeper soil gas containing more radon is brought up to the detection level. (The proposed

mechanism for earthquake related radon emanation variations will be discussed in more detail elsewhere.)

To obtain some quantitative estimate of the effect of a vertical soil gas flow on radon emanation, let us consider the one dimensional model by Clements¹¹. In this model the soil layer is considered to be a homogeneous porous half space (that is the lower boundary is much deeper than 10 m) with uniform radon production. Assume radon migrates vertically by a combination of the following two processes: (1) molecular diffusion governed by Fick's law and (2) gas flow governed by Darcy's law. Having taken into account the equation of continuity for radon and the boundary condition that radon concentration is 0 (negligibly small) at the ground surface, Clements obtained the following steady state result for radon concentration C as a function of depth ($-z$):

$$C = \frac{\phi}{\lambda} \left\{ 1 - \exp \left[\gamma \left(\frac{\varepsilon \lambda}{D} \right) z \right] \right\}$$

where

$$\gamma = \frac{v}{2(\varepsilon \lambda D)^{1/2}} + \left(\frac{v^2}{4\varepsilon \lambda D} + 1 \right)^{1/2},$$

ϕ is radon production rate, λ is its decay constant, ε is soil porosity, D is molecular diffusion coefficient of radon in the soil, and v is apparent soil gas flow velocity (volume of flow per unit time per unit geometric area). This result is shown in Fig. 3a for three different flow velocities and some material constants appropriate for typical dry soils. It is evident that a small vertical flow of soil gas (3×10^{-4} cm s⁻¹) can perturb significantly the subsurface radon concentration profile at shallow depths (< 10 m) such that the concentration at the depth of 0.7 m (monitoring depth of this study) is changed by a factor of 2.

To check whether subsurface radon concentration profile varies as predicted, we made radon measurements in boreholes

of several different depths separated by several metres at station 20. Figure 3b, shows the profiles for a 3-week period (week 96–98) during which the radon emanation was still anomalously high (see Fig. 2a), and for a 2-week period (week 99, 100) during which the emanation was nearly back to the average level. It is evident that during the anomalous period radon concentration increased at the shallower depths only, in agreement with the model.

If the observed temporal emanation variations are indeed earthquake related, why are they so large and so spatially coherent for earthquakes that are relatively small? One possibility is that the fault gouge zone, in which most of the radon stations are located, is mechanically much more compliant than the rocks on either side. As a result, strain changes may tend to concentrate in the fault zone over a long segment⁸. Similar spatial coherence is evident in some other fault-zone geophysical data, such as coseismic steps recorded on creepmeters at the times of local earthquakes of comparable magnitudes (> 4.0) (ref. 8) and fault zone deformation episodes indicated by data from alignment arrays¹².

This model may also explain the observed increase in radon emanation resulting from underground nuclear explosions¹³.

Structural comparison of glycophorins and immunochemical analysis of genetic variants

H. Furthmayr

Department of Pathology, Yale University School of Medicine, New Haven, Connecticut 06510

Differences in amino acid sequence of erythrocyte membrane glycophorin A are correlated with M or N blood group activity. A second sialoglycoprotein, glycophorin B, has an amino acid sequence identical to that of glycophorin A^N in the first 23 positions and carries N activity only, suggesting that different structural genes code for the glycoproteins carrying these antigens. Certain genetically variant cells lack glycophorin A, as determined by immunochemical methods, and serological MN activity. Other variants lack MN activity, but contain normal amounts of glycophorin A in the membrane.

LANDSTEINER and Levine¹ described a new blood group system in 1927, called MN, in which two alleles *M* and *N* determine the presence of corresponding antigens on the red cells. According to this two-allele theory, three genotypes are possible: *MM*, *MN* and *NN*. In 1947 an additional two-allele antigenic system *Ss* was found²; this is closely linked with *MN* and only rarely have recombination events been observed between *MN* and *Ss*³. The

antigens of the *MN* and *Ss* systems are probably found on different cell surface glycoproteins⁴. There are, however, other data which are inconsistent with this simple genetic interpretation of the serological data. *MM* homozygotes have been shown to express some *N* antigenic activity on the surface of their red cells; this becomes more readily detectable after proteolytic treatment of intact cells⁵. As neuraminidases destroy *MN* activity of human cells, it has been concluded that carbohydrates and sialic acid in particular are essential in the determinants⁶ and that the *MN* alleles code for glycosyltransferases^{7,8}. It has, however, also been shown that various reagents reacting with amino groups destroy *MN* activity and this has led to the idea that protein structures are part of the determinants^{3,4}.

Genetically variant cells have been described serologically, lacking one or the other antigen, and the question arose as to whether absence of the antigen(s) is caused by changes in carbohydrate structure or absence of the glycoproteins carrying the antigenic determinants. We report here studies on the primary structure of glycophorin A isolated from *M* and *N* homozygotes, and the amino terminal segment of glycophorin B. *MN* heterozygotes contain two different glycopeptides in their membrane, which possess different amino acids in positions 1 and 5. The

Fig. 1 Separation of tryptic peptides of glycoprotein A (a) and glycoprotein B (b) by gel filtration on Sephadex G150 superfine. 300 mg of glycoprotein A or glycoprotein B (fraction B in Fig. 1, ref. 21) isolated from pooled blood was dissolved in 30 ml of 50 mM Tris-HCl, pH 8.5 and was digested for 24 h with trypsin (TPCKT, Worthington) at an enzyme:substrate ratio of 1:30. After digestion, 3 mg of tosyl-L-Lys-CH₂Cl was added and the pH was adjusted to 4.5 with 1N HCl. The precipitate which formed during acidification was removed by centrifugation and the supernate, containing the soluble peptides, was freeze-dried and after resolubilisation was applied to a column of Sephadex G150 superfine (Pharmacia, Sweden), equilibrated in 0.1 M ammonium acetate at pH 6.8. The column dimensions were 2.4 cm × 150 cm, flow rate 10 ml h⁻¹, fraction volume approximately 5 ml. The column effluents were monitored for protein by measuring the absorbance at 230 nm (●), for sialic acid content by the procedure of Warren¹⁴ at 549 nm (○) and for tryptophan by measuring fluorescence emission at 355 nm (excitation 295 nm), (+).

glycopeptide isolated from glycoprotein B shares the amino acid sequence of glycoprotein A^N regardless of the MN type of the cell of origin. We further confirm previous suggestions that certain genetic variants at the MN locus entirely lack glycoprotein A⁹⁻¹¹, but genetically determined loss of MN activity is not necessarily correlated with the absence of glycoprotein A.

Glycoprotein A^M and glycoprotein A^N have different amino terminal sequences

In previous studies on the primary structure of glycoprotein A, two positions in the sequence consistently gave two amino acids: leucine and serine as the N-terminus and glycine and glutamic acid in position 5. In view of recent controversial findings⁴¹ and suggestions that glycoprotein A from M or N homozygous individuals contains predominantly one N-terminal residue, namely serine or leucine^{18,19}, we have reinvestigated the N-terminal structure of glycoprotein A isolated from two to five individuals, each with genotypes MM, MN, or NN.

Glycoprotein A was isolated by the LIS-phenol method²⁰ and gel filtration in detergent²¹. After tryptic digestion, the insoluble peptide portion was removed^{13,14} and the soluble peptides were separated by gel filtration (Fig. 1a)¹⁴. As described previously, two glycopeptides (T1 and T2) derived from the N-terminal end of the polypeptide chain, were found^{12,14,15}. Peptide T2 is obtained by cleavage at a lysyl and/or arginyl bond of part of the glycoprotein A molecules within the T1 sequence, which is insensitive to trypsin in T1. T2 is thus shortened at the C-terminal end by nine amino acid residues. T1 and T2 were re-

chromatographed by ion-exchange chromatography¹⁴. The yield of combined peptides T1 and T2 for each preparation was approximately 300 nmoles per unit of blood. The amino acid and carbohydrate composition of some of the peptides are given in Table 1. According to these data, T1 (not shown) and T2 from N homozygotes lack glycine, but contain one additional glutamic acid and leucine residue. The same peptides isolated from glycoprotein A from MN heterozygotes seem to be a mixture of both forms and the amino acid composition is comparable to that found in earlier studies^{12,14}. The carbohydrate composition of T1 (not shown), or T2 is rather similar for the three different preparations (Table 1).

The partial amino acid sequence was determined for the first 7 amino acid residues of T2 by simultaneously using the direct Edman degradation and dansyl-Edman procedure^{12,15}. The amino terminal sequence of glycoprotein A^M is Ser-Ser-Thr-Thr-Gly- as compared to glycoprotein A^N which has the sequence Leu-Ser-Thr-Thr-Glu-. The presence of both serine and leucine in position 1 and glycine and glutamic acid in position 5 for T2 isolated from glycoprotein A^{MN} indicates that this preparation is a mixture of the two types.

PTH-derivatives were not found in any preparation in steps 2, 3 and 4, and as described earlier, the finding of dansylated serine and threonine derivatives in these positions indicates that these residues are glycosylated^{12,15}. Figure 2 also contains the rest of the amino acid sequence of T2, which should be identical for all three preparations, since the amino acid composition does not indicate further heterogeneity and none was observed in this region of the sequence in our earlier studies^{12,15}. Quantitation of PTH-derivatives by gas chromatography was possible only for the non-glycosylated amino acids and we found for A^M-T2 90 nmol of serine in position 1, 13 nmol of glycine in position 5 and 64 nmol of valine in position 6. The uncorrected values of the amino acids found in these positions for A^N-T2 are 75, 39, and 23. No other amino acids were found, indicating that the isolated peptides are homogeneous with respect to the protein structure.

||Mol per mol peptide. Carbohydrates were determined as trimethylsilyl derivatives of methyl glycosides by gas-liquid chromatography, on a Hewlett-Packard 5110 B gas chromatograph, using inositol as an internal standard¹².

Fig. 2 Amino acid sequence and sites of glycosylation (* ●) of the N-terminal region of glycophorin A and glycophorin B. ↑ cleavage sites: cyanogen bromide (CN Br), trypsin (T) or chymotrypsin (CH). ←, residues identified after dansyl-Edman degradation by thin layer chromatography. →, residues identified as PTH-derivatives by gas-liquid chromatography. Except from positions 1 and 5, the one later code for amino acids is used⁴³.

N-terminal sequences of glycophorin A^N and glycophorin B are identical

Glycophorin B is not yet as well defined as glycophorin A. This sialoglycoprotein can be distinguished by its different electrophoretic mobility on SDS-polyacrylamide gels^{23,24}, amino acid composition²¹ and antigenic properties (refs 16, 17, and unpublished observations) and can be separated from glycophorin A by gel filtration in detergents²¹ or elution from SDS-polyacrylamide gels¹⁰. In certain genetically variant cells which lack both serological Ss activity and the trace N activity normally associated with *MM* homozygotes^{5,16}, periodic acid Schiff (PAS) staining bands in the glycophorin B positions are absent²⁹.

It has not yet been possible to isolate electrophoretically pure glycophorin B in preparative amounts. We decided therefore to use fractions B and C (Fig. 1 in ref. 21) obtained by gel filtration of the entire sialoglycoprotein fraction, as starting material for the isolation of glycopeptides. These fractions are highly enriched for glycophorin B, but contain variable amounts of a third and possibly other minor sialoglycoproteins, as suggested previously (refs 22–24, and unpublished observations). Figure 1b shows the chromatogram of the soluble peptides of a tryptic digest of fraction B. The two glycopeptides which elute in this system at positions identical to T1 and T2 of glycophorin A, were further purified by ion-exchange chromatography on DEAE-cellulose in 50 mM sodium formate, pH 6.1, and were eluted with a linear salt gradient (0–0.3 M NaCl). Under these conditions, peptides T1 (or T2) from glycophorin A are separated and thus contamination of the glycophorin B preparation with glycophorin A can easily be monitored.

Peptide B-T2 was also isolated as the major peptide component from a tryptic digest of fraction C (see Fig. 1 in ref. 21), which contains almost pure glycophorin B (data not shown). The amino acid and carbohydrate composition of glycopeptide B-T2 is given in Table 1, which shows that B-T2 is closely related to A-T2 in amino acid composition, but lacks mannose and N-acetyl glucosamine entirely. In contrast, B-T1 contains tryptophan, which is not found in glycophorin A, has an amino acid composition quite different from that of A-T1, but contains mannose and N-acetyl glucosamine (not shown). Further work will be required to establish whether it is derived from glycophorin B or yet another sialoglycoprotein.

We have determined the amino acid sequence of B-T2 by the methods described above. In order to accomplish this, B-T2 was desialated with neuraminidase and was cleaved with cyanogen bromide, trypsin and chymotrypsin^{12,14}, and the peptides indicated by arrows in Fig. 2 were obtained. A more detailed description of these data will be published elsewhere. The secondary peptides as well as B-T2 (steps 1–16) were subjected to manual Edman degradation and we found an amino acid sequence which was identical in at least the first 23–25 amino terminal residues to
